Abstract. We use a two sorted equational theory of algebraic effects to 6 model concurrent shared state with preemptive interleaving, recovering 7 Brookes's seminal 1996 trace-based model precisely. The decomposition 8 allows us to analyse Brookes's model algebraically in terms of separate q 10 but interacting components. The multiple sorts partition terms into layers. We use two sorts: a "hold" sort for layers that disallow interleaving 11 of environment memory accesses, analogous to holding a global lock on 12 the memory; and a "cede" sort for the opposite. The algebraic signature 13 comprises of independent interlocking components: two new operators 14 that switch between these sorts, delimiting the atomic layers, thought of 15 as acquiring and releasing the global lock; non-deterministic choice; and 16 17 state-accessing operators. The axioms similarly divide cleanly: the delimiters behave as a closure pair; all operators are strict, and distribute 18 over non-empty non-deterministic choice; and non-deterministic global 19 state obeys Plotkin and Power's presentation of global state. Our rep-20 resentation theorem expresses the free algebras over a two-sorted family 21 of variables as sets of traces with suitable closure conditions. When the 22 23 held sort has no variables, we recover Brookes's trace semantics.

27 **1** Introduction

4

We decompose Brookes's pioneering denotational model of concurrent shared 28 state under preemptive interleaving [7] using algebraic effects [33]. This model 29 possesses several desirable features in the area of denotational models for pro-30 gramming languages with concurrent features. (I) It is based on traces, an el-31 ementary sequential gadget. (II) It is fully compositional, as in traditional de-32 notational semantics for shared-state [14, 16, e.g.]. Each syntactic programming 33 construct, including parallel composition, has a corresponding semantic oper-34 ation combining the meanings of its constituents. Such full compositionality 35 contrasts with some recent models in this area that require additional 'seman-36 tic post-processing': some form of quotient, pruning of auxiliary mathematical 37

 $\mathbf{2}$

constructs, reasoning up-to behavioural equivalence; or capture only sequen-38 tial blocks, reasoning about the parallel composition on a separate layer [e.g. 39 8, 9, 18, 23. (III) Subsequent variations and extensions [5, 42, 43], as well as 40 adaptations to relaxed memory models [13, 23], attest to its versatility, making 41 it a cornerstone in the denotational semantics for concurrent languages with 42 side-effects. (IV) It achieves a high level of abstraction, evident in the many 43 compiler transformations that the model supports, including the most common 44 memory access introductions and eliminations, and the laws of parallel program-45 ming. Moreover, Brookes showed the model to be fully abstract in a language 46 extended with the await construct, which blocks execution until all memory 47 locations contain a given tuple of values, and then atomically updates them to 48 contain another tuple of values. This construct is not a natural programming 49 construct, but is clearly suggested by Brookes's semantics. 50

Plotkin and Power's modern theory of *algebraic effects* [33] refines Moggi's 51 monadic approach [28] with algebraic theories. The algebraic approach informs 52 the monadic structure by identifying semantic counterparts to syntactic con-53 structs and axiomatising their semantics equationally. The monadic structure 54 emerges through the well-established connection between algebraic theories and 55 monads [25] via representation theorems. For example: global state emerges by 56 axiomatising memory lookup and update [33] and a representation theorem in-57 volving the state monad; non-determinism emerges by axiomatising semi-lattices 58 and a representation theorem involving the powerdomains [14, 30]; and so on. 59 The algebraic perspective may offer insights into the making of the denotational 60 semantics. It can suggest methods for combining different effects and modularly 61 augment a semantics with a given computational effect [16]. 62

Contribution Our main conceptual contribution is to exhibit Brookes's model 63 algebraically. The connection between algebraic effects and concurrency has long 64 been emphasised. For example, the ability to use algebraic effects, without any 65 axioms, and their effect handlers [4, 35, 36] to allow users to define their own 66 schedulers was the original motivation for their implementation in the OCaml 67 programming language [10, 11, 38]. Nonetheless, exhibiting abstract models such 68 as Brookes's algebraically via equational axiomatisation of syntactic constructs 69 has proved challenging. Our own previous algebraic model [12] invalidates a key 70 transformation, reflecting a fundamental limitation of it. 71

Our main technical innovation is to use multi-sorted algebraic theories, a 72 direction that was raised in personal discussions since the earliest work on alge-73 braic effects [33]. A multi-sorted algebraic term decomposes into layers. Our two 74 sorts represent two modes of interaction between a program fragment and its 75 concurrent environment. A "hold" sort provides a reasoning layer in which the 76 environment may not interfere, whereas in the "cede" sort it may. We provide 77 two operators that switch between these sorts, allowing our axioms to specify 78 the uninterruptable effects. Our core idea is to axiomatise these operators as a 79 80 closure pair, an established order-theoretic special Galois-connection, the dual to the domain-theoretic embedding-projection pairs [2]. The remaining axioms 81 are strikingly independent from these axioms, and cover the strict distributive 82

- ⁸³ interaction of global state with non-determinism and the strict distributivity
- ⁸⁴ of the closure pair over non-determinism. Our main technical contribution is
- the representation of this theory, which uses sets of traces akin to Brookes's,
- ⁸⁶ recovering Brookes's model precisely in the "cede" sort.
- ⁸⁷ Summarising, our contributions are as follows:
- $_{88}$ A two-sorted algebraic theory for shared-state, **S**.
- $_{89}~-$ A representation theorem for ${\ensuremath{\$}}$ via Brookes-style trace sets.
- $_{90}$ A decomposition of Brookes's model using **S** and a geometric morphism.
- $_{91}$ A single-sorted algebraic theory for Brookes's await, embedding into **S**.
- $_{92}$ The first use of multi-sorted theories for algebraic effects

Caveats Throughout the development, we opt for mathematical simplicity wher-93 ever possible. For example, we use countable-join semilattices instead of finite-94 join semilattices to represent non-determinism. This choice streamlines the de-95 velopment leading up to the main technical contribution—the representation 96 theorem—allowing us to use countable sets instead of finitely generated ones. 97 We also do not treat recursion to avoid the complexity a domain-theoretic ac-98 count will incur. The resulting model—identical to Brookes's—coincides with 90 the elided domain-theoretic model over discrete pre-domains. This model also 100 supports iteration (i.e. while-loops) without change thanks to countable-joins. 101 It also supports first-order recursion without change by equipping it with a 102 domain-theoretic structure. These compromises let us focus on the core con-103 cepts, and provide a relatively elementary mathematical exposition and a clear 104 presentation of the underlying idea, motivating future inquiry. 105

Outline In §2 we recap notions of multi-sorted algebra. In §3 we present our 106 two-sorted theory of shared state. In §4 we build a free-model representation of 107 this theory, an adaptation of Brookes's model. In §5 we recover Brookes's model 108 precisely, using two different methods that offer different perspectives: model-109 theoretically, via an adjunction with the representation; and algebraically, via an 110 embedding of a single-sorted theory of transitions for Brookes's model. Finally, 111 we conclude in §6, where we discuss related work, as well as further research 112 opportunities our contributions enables. 113

The supplementary material also includes in appendix A some "no-go" results concerning single-sorted theories, motivating the use of a multi-sorted theory to solve the problem at hand. For example, it shows why a natural single-sorted theory—axiomatising yielding as closure operator—cannot work.

118 2 Preliminaries

¹¹⁹ In the algebraic effects approach to denotational semantics, we: express core ¹²⁰ effectful programming constructs as corresponding algebraic operations; express ¹²¹ core equational axioms between them as axioms for algebraic structures; and ¹²² derive a monad by representing the free-model over sets of variables, and define a ¹²³ denotational semantics with it. This section is a standard treatment of countably-¹²⁴ infinitary multi-sorted equational theories and their free models [3, 41, e.g.].

125 2.1 Terms

4

We define the logical language of multi-sorted equational logic. The basic vo-126 cabulary of multi-sorted algebra is parameterised by a set **sort** whose elements 127 \square , \diamondsuit we call sorts. We will mostly focus on the single-sorted case (sort = { \star }) 128 and the two-sorted case (sort = $\{\bullet, o\}$). A sorting scheme $\vec{u} \in \text{Scheme sort}$ is 129 a countable sequence of sorts, e.g. a finite sequence $\vec{\Box} = \langle \Box_0, \dots, \Box_{n-1} \rangle$ of length 130 n, or countably infinite sequence $\vec{\mathbf{a}} = \langle \mathbf{a}_0, \mathbf{a}_1, ... \rangle$ of length ω . For example: the 131 empty scheme $\mathbf{0} := \langle \rangle$ of length 0; and the constant schemes $\alpha \cdot \Box := \langle \Box \rangle_{i < \alpha}$ of 132 length α . We write \square for the scheme $1 \cdot \square$. 133

A sort-sorted signature $\Sigma = \langle \mathbf{op}_{\Sigma}, \mathbf{ar}_{\Sigma} \rangle$ consists of a set of operators \mathbf{op}_{Σ} and an arity assignment $\mathbf{ar}_{\Sigma} : \mathbf{op}_{\Sigma} \to \mathbf{sort} \times \mathbf{Scheme \ sort}$. For $O \in \mathbf{op}_{\Sigma}$ with $\mathbf{ar}_{\Sigma} O = \langle \Box, \langle \diamondsuit_i \rangle_i \rangle$, we write $(O : \Box \langle \diamondsuit_i \rangle_{i < \alpha}) \in \Sigma$. The operator O will allow us to construct a \Box -sort term with a tuple of terms, with the *i*th subterm having sort \diamondsuit_i . For single-sorted arities ($\mathbf{sort} = \{ \star \}$), we write $O : \alpha$ for $O : \star (\alpha \cdot \star)$. A signature is a set \mathbf{sort}_{Σ} and a \mathbf{sort}_{Σ} -sorted signature we also denote by Σ .

¹⁴⁰ We will use the following signature to model non-deterministic choice.

Example 1. The *join semilattice* single-sorted signature J consists of two operators: *join* \lor : **2**, i.e. \lor : $\star \langle \star, \star \rangle$ and *bottom* \bot : **0**, i.e., \bot : $\star \langle \rangle$.

To simplify the formulation of our representation theorem later, we generalize the signature to countable non-deterministic choice operators:

¹⁴⁵ Example 2. The countable-join semilattice single-sorted signature V consists of ¹⁴⁶ an α -ary choice operator $\bigvee_{\alpha} : \alpha$ for every $\alpha \leq \omega$. In particular, the signature J ¹⁴⁷ is included with $\alpha = 2$ (join) and $\alpha = 0$ (bottom).

¹⁴⁸ The final example demonstrates the treatment for multiple sorts:

Example 3. The *finite dimensional transformations* signature M consists of a sort for each pair of natural numbers $\operatorname{sort}_{\mathsf{M}} := \{\operatorname{Hom}(m, n) \mid m, n \in \mathbb{N}\}$, an identity operator $\operatorname{Id}_n : \operatorname{Hom}(n, n)$ for each $n \in \mathbb{N}$, and, for each triple $m, n, k \in \mathbb{N}$, a composition operator $(\circ_{m,n,k}) : \operatorname{Hom}(m,k) \langle \operatorname{Hom}(n,k), \operatorname{Hom}(m,n) \rangle$.

A signature generates a language of algebraic terms as follows. A sortfamily $X \in \mathbf{Set}^{\mathbf{sort}}$ is an assignment of a set X_{\square} , to each sort $\square \in \mathbf{sort}$. We identify $\mathbf{Set}^{\{\star\}} \cong \mathbf{Set}$, and use a set-like notation to specify families, e.g. $X := \{x : \bullet, y, z : \bullet\}$ is the two-sorted family $X_{\bullet} := \{x\}$ and $X_{\circ} := \{y, z\}$. We can turn³ every sort-family X into the set $\oint X := \coprod_{\square \in \mathbf{sort}} X_{\square}$ equipped with the injections $\operatorname{in}_{\square} : X_{\square} \to \oint X$.

For a signature Σ and $\operatorname{sort}_{\Sigma}$ -family $X \in \operatorname{Set}^{\operatorname{sort}_{\Sigma}}$, define the $\operatorname{sort}_{\Sigma}$ -family of Σ -terms over X: $\operatorname{Term}^{\Sigma} X \in \operatorname{Set}^{\operatorname{sort}_{\Sigma}}$, $\operatorname{Term}^{\Sigma}_{\Box} X := \{t \mid X \vdash_{\Sigma} t : \Box\}$ inductively:

$$\frac{(x:\square) \in \mathbf{X}}{\mathbf{X} \vdash_{\Sigma} x:\square} \qquad \frac{(O:\square \left\langle \diamondsuit_i \right\rangle_{i < \alpha}) \in \Sigma \quad \forall i. \, \mathbf{X} \vdash_{\Sigma} t_i : \diamondsuit_i}{\mathbf{X} \vdash_{\Sigma} O \left\langle t_i \right\rangle_{i < \alpha} : \square}$$

³ This simple construction is a special case of the Grothendieck construction, and lets us track the distinction between sets and families.

Here, the elements $x \in X_{\square}$, written $(x : \square) \in X$, represent variables of sort \square .

A sort-sorted map $f: \mathbf{X} \to \mathbf{Y}$ is a sort-indexed tuple of functions between the corresponding sets: $f_{\square}: \mathbf{X}_{\square} \to \mathbf{Y}_{\square}$, for every $\square \in$ sort. Most of our development will utilise such sorted maps, and for now we will use them to define the standard notion of simultaneous substitution. A substitution $\mathbf{X} \vdash_{\Sigma} \theta : \mathbf{Y}$ is a sorted function $\theta: \mathbf{Y} \to$ Term^{Σ} \mathbf{X} , specifying which \square -term $\mathbf{X} \vdash_{\Sigma} \theta_{\square} y : \square$ to substitute for each variable $y \in \mathbf{Y}_{\square}$. Each such substitution determines a sorted map $[\theta]:$ Term $\mathbf{Y} \to$ Term \mathbf{X} inductively, which we write in post-fix notation:

$$\left(\boldsymbol{Y}\vdash_{\Sigma}\boldsymbol{y}:\boldsymbol{\Box}\right)\left[\boldsymbol{\theta}\right] \coloneqq \left(\boldsymbol{X}\vdash_{\Sigma}\boldsymbol{\theta}_{\boldsymbol{\Box}}\boldsymbol{y}:\boldsymbol{\Box}\right) \qquad \left(\boldsymbol{Y}\vdash_{\Sigma}O\left\langle t_{i}\right\rangle_{i}\right)\left[\boldsymbol{\theta}\right] \coloneqq \left(\boldsymbol{X}\vdash_{\Sigma}O\left\langle t_{i}\left[\boldsymbol{\theta}\right]\right\rangle_{i}\right)$$

¹⁶⁹ 2.2 Equational logic

170 A \square -sorted Σ -equation in context X consists of a pair $\langle l, r \rangle \in \operatorname{Term}_{\square}^{\Sigma} X$ of \square -171 sorted Σ -terms over X. We write this situation as $X \vdash_{\Sigma} l = r : \square$, and call l172 the left-hand side (LHS) and r the right-hand side (RHS) of the equation. A 173 presentation \mathfrak{p} consists of a signature $\Sigma_{\mathfrak{p}}$ and axioms: a set $\operatorname{Ax}_{\mathfrak{p}}$ of Σ -equations.

Example 4. The join semilattice presentation J consists of the signature $\Sigma_{J} := J$ of example 1, and the axioms Ax_{J} below, where variables and sorts are omitted:

$$\begin{array}{ll} \text{(Associativity)} & x \lor (y \lor z) = (x \lor y) \lor z & \text{(Idompotency)} & x \lor x = x \\ \text{(Commutativity)} & x \lor y = y \lor x & \text{(Neutrality)} & x \lor \bot = x & \Box \end{array}$$

177 Example 5. The countable-join semilattice presentation V consists of the signa-

ture $\Sigma_{\mathsf{V}} := \mathsf{V}$ of example 2, and the axioms $\operatorname{Ax}_{\mathsf{V}}$, omitting variables and sorts: (ND-return) $\bigvee_{i < 1} x_i = x_0$

(ND-squash)
$$\bigvee_{i < \alpha} \bigvee_{j < \beta_i} x_{i,j} = \bigvee_{k < \gamma} x_{fk}$$
 where $f : \gamma \twoheadrightarrow \coprod_{i < \alpha} \beta_i$

¹⁸⁰ Example 6. The finite dimensional transformations presentation M consists of ¹⁸¹ the signature $\Sigma_{M} := M$ of example 3 and the axioms Ax_{M} below, omitting variables ¹⁸² and sorts, as well as suppressing the sort indices (each axiom scheme includes ¹⁸³ every possible instantiation):

Figure 1 presents the deductive system called *equational logic*. We say that a presentation \mathfrak{p} proves an equation, writing $\mathbf{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \Box$ when it is derivable from $Ax_{\mathfrak{p}}$ using these standard equational reasoning rules, namely: reflexivity, symmetry, transitivity, use of an axiom, substitution, and congruence. This logic is monotone: assuming more axioms allows us to prove more equations. The *algebraic theory* of a presentation \mathfrak{p} is the smallest deduction-closed set of equations containing the axioms.

Example 7. We can prove $\{x, y : \star\} \vdash_{\mathsf{J}} (x \lor \bot) \lor y = x \lor y : \star$ using an instance of Neutrality and reflexivity with the following instance of congruence:

$$\{z,y:\star\}\vdash_{\mathsf{J}}t:=z\vee y\qquad \theta_1:=\binom{z\mapsto x\vee\bot}{y\mapsto y}\qquad \theta_2:=\binom{z\mapsto x}{y\mapsto y}\qquad \Box$$

 $\mathbf{6}$

$$\begin{split} \frac{\boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} t: \square}{\boldsymbol{X} \vdash_{\mathfrak{p}} t = t : \square} & \frac{\boldsymbol{X} \vdash_{\mathfrak{p}} t_2 = t_1 : \square}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} & \frac{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} \\ \frac{(\boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} t_1 = t_2 : \square) \in \operatorname{Ax}_{\mathfrak{p}}}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} & \frac{\boldsymbol{Y} \vdash_{\mathfrak{p}} t_1 = t_2 : \square & \boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} \theta : \boldsymbol{Y}}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} \\ \frac{(\boldsymbol{Y} \vdash_{\Sigma_{\mathfrak{p}}} t: \square & \boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} \theta_1, \theta_2 : \boldsymbol{Y}}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} & \frac{\boldsymbol{Y} \vdash_{\mathfrak{p}} t_1 = t_2 : \square & \boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} \theta : \boldsymbol{Y}}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 [\theta] = t_2 [\theta] : \square} \\ \frac{\boldsymbol{Y} \vdash_{\Sigma_{\mathfrak{p}}} t: \square & \boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} \theta_1, \theta_2 : \boldsymbol{Y}}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} & \forall (y : \diamond) \in \boldsymbol{Y}. \boldsymbol{X} \vdash_{\mathfrak{p}} \theta_1 y = \theta_2 y : \diamond}{\boldsymbol{X} \vdash_{\mathfrak{p}} t_1 = t_2 : \square} \end{split}$$

Fig. 1. Multi-sorted equational logic with countable arities

When a presentation \mathfrak{p} proves the semi-lattice axioms in one of its sorts \square , then the encoding $(\mathbf{X} \vdash_{\Sigma_{\mathfrak{p}}} l \leq r : \square) := (\mathbf{X} \vdash_{\Sigma_{\mathfrak{p}}} l \lor r = r : \square)$ of inequations as equations in this sort is a preorder w.r.t. \mathfrak{p} -equality, i.e.

$$(\boldsymbol{X}\vdash_{\mathfrak{p}} s\leq t\leq s:\mathbf{\Box})\implies (\boldsymbol{X}\vdash_{\mathfrak{p}} s=t:\mathbf{\Box})$$

We use similar encoding for (\geq) . Due to the monotonicity property of equational logic, once we have included an axiomatization of semi-lattices through a subset of the axioms, we may proceed to postulate inequations.

We will also use a generalisation of distributivity axioms, reproducing familiar arithmetic distributivity equations such as $x \cdot \max\{y_1, y_2\} = \max\{x \cdot y_1, x \cdot y_2\}$, the distributivity of (·) over max in the right-hand-side position. The generalization is straightforward, but technical. The main message: in a given presentation \mathfrak{p} , if all operators distribute over binary joins in every position, the congruence rule is valid for inequations:

$$\frac{\boldsymbol{Y} \vdash_{\Sigma_{\mathfrak{p}}} t: \square \qquad \boldsymbol{X} \vdash_{\Sigma_{\mathfrak{p}}} \theta_1, \theta_2: \boldsymbol{Y} \qquad \forall (y: \Diamond) \in \boldsymbol{Y}. \boldsymbol{X} \vdash_{\mathfrak{p}} \theta_1 y \leq \theta_2 y: \Diamond}{\boldsymbol{X} \vdash_{\mathfrak{p}} t\left[\theta_1\right] \leq t\left[\theta_2\right]: \square}$$

If a presentation **p** supports semi-lattices in every sort and they distribute over bi-206 nary joins in every positions, then we say that **p** supports inequational reasoning. 207 The theory of \mathfrak{p} then admits Bloom's logic for ordered algebraic theories [6]. We 208 let future work determine the most appropriate variety of inequational logic [32]. 209 Going forward, all of our presentations support inequational reasoning in this 210 sense, and all operators distribute over arbitrary non-empty joins, not just the 211 binary ones. Moreover, they are all strict: $O(\perp, ..., \perp) = \perp$ for every operator 212 $(O: \square \langle \Diamond_i \rangle_{i < \alpha}) \in \Sigma_p$. Such theories 'absorb' side-effects when their continuations 213 diverge, an inherent 'partial correctness' property of Brookes's model. 214 The rest of this section is devoted to the technical definition of distributivity. 215

Let Σ be a multi-sorted signature, $(P : \Box \langle \diamond_i \rangle_{i < \alpha}) \in \Sigma$ be an operator, and $i_0 < \alpha$ be one of the positions in P's scheme. Assume further such that both \diamond_{i_0} and \Box have 'single-sorted' operators $(S : \diamond_{i_0} (\beta \cdot \diamond_{i_0})), (S' : \Box (\beta \cdot \Box)) \in \Sigma$ with the same arity length β . We define the following *distributivity* axiom [17]:

$$\begin{split} \{x_i: \otimes_i \mid i_0 \neq i < \alpha\} \cup \left\{y_j: \otimes_{i_0} \mid j < \beta\right\} \vdash_{\Sigma} \\ P \left\langle \begin{cases} i \neq i_0: & x_i \\ i = i_0: & S \left\langle y_j \right\rangle_j \end{cases}_i = S' \left\langle P \left\langle \begin{cases} i \neq i_0: & x_i \\ i = i_0: & y_j \right\rangle_i \right\rangle_j : \square \end{cases} \right\rangle \end{split}$$

which we call the distributivity of P over S, S' in the i_0 -component.

Distributivity over binary joins implies monotonicity, in the following sense. Let \mathfrak{p} be a presentation, $(O : \Box \langle \diamondsuit_i \rangle_{i < \alpha}) \in \Sigma_{\mathfrak{p}}$ be an operator, and $i_0 < \alpha$ an index into its sorting scheme. Assume \Box, \diamondsuit_{i_0} include the theory of semilattices, and that O distributes over the binary joins of \diamondsuit_{i_0} and \Box in the i_0^{th} component. Then O is monotone in this component w.r.t. the semilattice preorder, i.e., the following deduction rule is admissible:

$$\frac{\boldsymbol{Y} \vdash_{\mathfrak{p}} l \leq r : \diamond_{i_0}}{\{x_i : \diamond_i \mid i_0 \neq i < \alpha\} \cup \boldsymbol{Y} \vdash_{\mathfrak{p}} O\left\langle \begin{cases} i \neq i_0 : x_i \\ i = i_0 : l \end{cases} \right\rangle_i \leq O\left\langle \begin{cases} i \neq i_0 : x_i \\ i = i_0 : r \end{cases} \right\rangle_i$$

Specifically, if p includes the theory of semilattices in all sorts, and every operator
 distributes over binary joins, then the congruence rule for inequations is valid.

229 2.3 Algebras and models

After presenting the proof theory—equational logic—lets turn to the model theory of universal algebra. A Σ -algebra \mathbf{A} consists of a \mathbf{sort}_{Σ} -family $\underline{\mathbf{A}} \in \mathbf{Set}^{\mathbf{sort}_{\Sigma}}$, the carrier, and an assignment $\mathbf{A} \llbracket - \rrbracket_{\mathrm{op}}$, for each operator $(O : \Box \langle \diamondsuit_i \rangle_{i < \alpha}) \in \Sigma$, of an operation over this carrier: $\mathbf{A} \llbracket O \rrbracket_{\mathrm{op}} : (\prod_{i < \alpha} \underline{\mathbf{A}}_{\diamondsuit_i}) \to \underline{\mathbf{A}}_{\Box}$.

Example 8. For any set X, define the V-algebra $\mathbf{V}X$ by taking the carrier to be the set of countable (finite or infinite) X-subsets $\underline{\mathbf{V}X} := \mathbf{P}^{\aleph_0}(X)$, and interpret choice as union $\mathbf{L}X[[V_{\alpha}]]_{\mathrm{op}}\langle D_i \rangle_{i < \alpha} := \bigcup_{i < \alpha} D_i$.

²³⁷ Example 9. Define the M-algebra **M** by taking the carrier to be the set of real-²³⁸ valued matrices of the corresponding dimensions, $\underline{\mathbf{M}}_{\mathbf{Hom}(m,n)} := \mathbb{M}_{m \times n}^{\mathbb{R}}$, interpret ²³⁹ the identity $\mathbf{M}[\![\mathrm{Id}_n]\!]_{\mathrm{op}} := I_n \in \mathbb{M}_{n \times n}^{\mathbb{R}}$ as the identity matrix, and composition ²⁴⁰ $\mathbf{M}[\![(\circ)]\!]_{\mathrm{op}} := (\cdot)$ as matrix multiplication.

Let \mathbf{A} be an M-algebra. Define the *opposite* algebra \mathbf{A}^{op} by exchanging dimensions. So $\mathbf{A}_{\mathbf{Hom}(m,n)}^{\mathsf{op}} \coloneqq \mathbf{A}_{\mathbf{Hom}(n,m)}^{\mathsf{op}}$, the same identity $\mathbf{A}^{\mathsf{op}} \llbracket \mathrm{Id}_n \rrbracket_{\mathsf{op}} \coloneqq \mathbf{A} \llbracket \mathrm{Id}_n \rrbracket_{\mathsf{op}},$ and reversing composition $\mathbf{A}^{\mathsf{op}} \llbracket (\circ) \rrbracket_{\mathsf{op}}(A, B) \coloneqq \mathbf{A} \llbracket (\circ) \rrbracket_{\mathsf{op}}(B, A).$

244 Example 10 (term algebra). The Σ-terms with variables from \boldsymbol{X} carry a canonical algebra structure $\mathbf{F}^{\Sigma}\boldsymbol{X}$, given by $\mathbf{F}^{\Sigma}\boldsymbol{X} := \operatorname{Term}^{\Sigma}\boldsymbol{X}$, with each O-term constructor as the corresponding O-operation: $(\mathbf{F}^{\Sigma}\boldsymbol{X}) \llbracket O \rrbracket_{\mathrm{op}} \langle t_i \rangle_i := O \langle t_i \rangle_i$.

²⁴⁷ A Σ -algebra allows us to interpret every Σ -term, given values for its variables. ²⁴⁸ Formally, let **A** be a Σ -algebra. An **X**-environment in **A** is a sorted function $e : X \to \underline{A}$. Given such an environment, we can interpret every term by induction:

$$\mathbf{A} \begin{bmatrix} \mathbf{X} \vdash_{\Sigma} x : \mathbf{\Box} \end{bmatrix}_{\text{term}} e \coloneqq e_{\mathbf{\Box}} x \qquad \mathbf{A} \begin{bmatrix} O \left\langle t_i \right\rangle_i \end{bmatrix}_{\text{term}} e \coloneqq \mathbf{A} \begin{bmatrix} O \end{bmatrix}_{\text{op}} \left\langle \mathbf{A} \begin{bmatrix} t_i \end{bmatrix}_{\text{term}} e \right\rangle_i$$

Example 11 (substitution). An X-environment in $\mathbf{F}^{\Sigma} X$ amounts to a substitution, and interpreting terms in $\mathbf{F}^{\Sigma} X$ amounts to substitution.

A Σ -algebra \mathbf{A} validates the equation $\mathbf{X} \vdash_{\Sigma} l = r : \square$ when evaluation in all environments equates its sides: $\mathbf{A}[\![l]\!]_{\text{term}} e = \mathbf{A}[\![r]\!]_{\text{term}} e$ for all $e : \mathbf{X} \to \underline{\mathbf{A}}$. We then write $\mathbf{A} \vdash \mathbf{X} \vdash_{\Sigma} l = r : \square$. A \mathfrak{p} -model is an algebra validating all of $A_{\mathbf{x}_{\mathfrak{p}}}$. The soundness theorem of equational logic states that every \mathfrak{p} -model validates all the equations in the algebraic theory of \mathfrak{p} .

²⁵⁷ Example 12. Referring to previous examples, the algebras VX are V-models, the ²⁵⁸ algebras **M** and **M**^{op} are M-models, and the algebra of terms is an \emptyset -model. \Box

Example 13. Consider the Σ_{J} -algebra \mathbf{A} for which the carrier is the set of natural numbers $\underline{\mathbf{A}} := \mathbb{N}$, join interprets as addition $\mathbf{A}[\![\vee]\!]_{\mathrm{op}}(m,n) := m+n$, and bottom as zero $\mathbf{A}[\![\bot]\!]_{\mathrm{op}} := 0$. This is not a J -model, since, taking $e : \{x : \star\} \to \underline{\mathbf{A}}$ with ex = 1, we get $\mathbf{A}[\![x \lor x]\!]_{\mathrm{term}} e \neq \mathbf{A}[\![x]\!]_{\mathrm{term}} e$; and so $\mathbf{A} \not\vdash x : \star \vdash_{\mathsf{J}} x \lor x = x : \star$. \Box

263 2.4 Representability

8

The final concept we need is the representation of free models. It specifies when the elements in a given \mathfrak{p} -model represent the $\Sigma_{\mathfrak{p}}$ -terms up-to provable equality in \mathfrak{p} . Our main technical contribution (§4) is to show that Brookes's trace semantics, generalised appropriately, is the free model for a two-sorted algebraic theory.

A Σ -algebra homomorphism $\varphi : \mathbf{A} \to \mathbf{B}$ is a sorted-function $\varphi : \underline{\mathbf{A}} \to \underline{\mathbf{B}}$ that preserves the operations: $\varphi(\mathbf{A} \llbracket O \rrbracket_{\mathrm{op}} (a_1, \dots, a_{\alpha})) = \mathbf{B} \llbracket O \rrbracket_{\mathrm{op}} (\varphi a_1, \dots, \varphi a_{\alpha}).$

Example 14. Transposing real-valued matrices $(-)^{\top} : \mathbb{M}_{m \times n}^{\mathbb{R}} \to \mathbb{M}_{n \times m}^{\mathbb{R}}$ is a homomorphism $(-)^{\top} : \mathbf{M} \to \mathbf{M}^{\mathsf{op}}$, by the well-known identity $(A \cdot B)^{\top} = B^{\top} \cdot A^{\top}$. \Box

272 Example 15 (evaluation homomorphism). Evaluation using any X-environment 273 $e: \mathbf{X} \to \underline{\mathbf{A}}$ in a Σ -algebra \mathbf{A} is a homomorphism $\mathbf{A}[\![-]\!]_{\text{term}} e: \mathbf{F}^{\Sigma} \mathbf{X} \to \mathbf{A}$. \Box

A \mathfrak{p} -model $\langle \mathbf{A}, e \rangle$ over a family \mathbf{X} consists of a \mathfrak{p} -model \mathbf{A} and an \mathbf{X} -environment in it $e : \mathbf{X} \to \underline{\mathbf{A}}$. A free \mathfrak{p} -model $\langle \mathbf{A}, \operatorname{return} \rangle$ over a family \mathbf{X} is then a \mathfrak{p} -model over \mathbf{X} such that every environment in every \mathfrak{p} -model $e : \mathbf{X} \to \underline{\mathbf{B}}$ extends uniquely along return to a \mathfrak{p} -homomorphism $e^{\#} : \mathbf{A} \to \mathbf{B}$, i.e., for all $x \in \mathbf{X}_{\Box}$, we have: $e_{\Box}^{\#}(\operatorname{return}_{\Box} a) = ea$. We then say that the algebra \mathbf{A} represents \mathbf{X} -environments via the assignment $e \mapsto e^{\#}$, the corresponding representation.

The algebraic theory of effects [33] emphasises the role free models play in denotational semantics for programming languages with effects. In particular, given a free p-model over X for every family X, one standardly obtains a monad suitable for the denotational semantics of a language with computational effects conforming to the operators in p.

Example 16. For any set X, the V-algebra $\mathbf{V}X$ given by the countable powerset in example 8 represents X-environments; together with return $x := \{x\}$ it forms a free V-model over X. The representation assigns $e : X \to \underline{\mathbf{B}}$ to $e^{\#} : \mathbf{V}X \to \mathbf{B}$, $e^{\#}D := \bigcup_{x \in D} ex$. The data $\langle X \mapsto \underline{\mathbf{V}X}$, return, $(-)^{\#} \rangle$ is a monad. \Box

289 3 Shared state

304

To define the equational theory of shared state, we first recall the standard, 290 single sorted (non-deterministic) global state theory G [16, 27, 33]. The variant 291 we present here has countable non-determinism, and the global state operators 292 manipulate a common memory store $\mathbb{S} := \mathbb{L} \to \mathbb{B}$ with a finite set of locations 293 $\mathbb{L} \neq \emptyset$ each storing a bit $\mathbb{B} := \{0, 1\}$. A larger finite set of storable-values would 294 not be conceptually different. Infinite sets of storable-values or locations work 295 similarly with more involved representation theorems. In concrete examples, we 296 let $\mathbb{L} = \{\mathbf{l}_1, \mathbf{l}_2\}$ and use non-bracketed vectors for stores, e.g. $\frac{1}{0}$ denotes $\begin{pmatrix} \mathbf{l}_1 \mapsto \mathbf{l} \\ \mathbf{l}_2 \mapsto \mathbf{0} \end{pmatrix}$. 297 The signature Σ_{G} consists of the countable-join semilattice operators (ex-298 ample 2), as well as two kinds of memory-access operators: lookup operators 299 $L_{\ell}: \star \langle \star, \star \rangle$, to look a location $\ell \in \mathbb{L}$ up and branch according to the value 300 found; and *update* operators $U_{\ell,b}$: $\star \langle \star \rangle$, to update a location $\ell \in \mathbb{L}$ to the value 301 $b \in \mathbb{B}$. The global state axioms Ax_G consists of the countable-join semilattice 302 axioms (example 5), as well as the following: 303

	Non-deterministic global state (omitting semilattice axioms)		
(UL) (UU) (UUc)	$\begin{array}{c} U_{\ell,b} L_{\ell}(x_0, x_1) = U_{\ell,b} x_b \\ U_{\ell,b'} U_{\ell,b} x = U_{\ell,b} x \\ U_{\ell,b} U_{\ell',b'} x = U_{\ell',b'} U_{\ell,b} x \end{array}$	$\begin{array}{c} (\mathrm{LU}) & L_{\ell}(U_{\ell,0}x,U_{\ell,1}x) = x \\ (\mathrm{ND}\text{-}U) & \bigvee_{i < \alpha} U_{\ell,b}x_i = U_{\ell,b} \bigvee_{i < \alpha} x_i \\ \text{where } \ell \neq \ell' \end{array}$	

The induced algebraic theory [33] includes other familiar axioms [27]. For example, lookup also distributes over binary join, so the theory admits inequational reasoning; consecutively looking the same location up can be merged, e.g. $\{x_0, x_1, y\} \vdash_{\mathsf{G}} \mathsf{L}_{\ell}(\mathsf{L}_{\ell}(x_0, x_1), y) = \mathsf{L}_{\ell}(x_0, y)$; and other combinations of looking-up and updating different locations commute, e.g. for any $\ell \neq \ell'$ we have $\{x_0, x_1\} \vdash_{\mathsf{G}} \mathsf{L}_{\ell}(\mathsf{U}_{\ell', b} x_0, \mathsf{U}_{\ell', b} x_1) = \mathsf{U}_{\ell', b} \mathsf{L}_{\ell}(x_0, x_1)$.

Our two-sorted presentation **S** of *shared state* extends global state. Its sorts are **sort**_{$\Sigma_{\mathbf{s}}$} = {•, •}. The *hold* sort (•) represents an uninterrupted sequence of memory accesses, whereas the *cede* sort (•) allows control to pass to the environment. The operators and the arities of the signature $\Sigma_{\mathbf{s}}$ consist of a copy of $\Sigma_{\mathbf{G}}$ at •, a copy of $\Sigma_{\mathbf{V}}$ at •, and new operators $\lhd : \circ \langle \bullet \rangle$ and $\triangleright : \bullet \langle \circ \rangle$.

The intuitive reading for algebraic effects is from the outside in. With this 316 intuition, one interpretation of the operators \triangleleft and \triangleright is to acquire and release a 317 global lock. The hold sort (\bullet) represents the lock being held by one of the threads 318 in the program. The cede sort (\circ) represents points in the execution in which one 319 of the threads in the concurrent environment may acquire the lock. The sorts 320 ensure exclusive access to the lock, and therefore to the store. In an alternative 321 interpretation, these operators delimit atomic blocks, their sorts prevent nesting. 322 The shared state axioms Ax₅ include a copy of the (non-deterministic) global 323

state axioms Ax_G at • and a copy of the countable-join semilattice axioms Ax_V at •. In particular, **S** proves the semi-lattice axioms in both sorts. It further includes standard strict distributivity axioms for the new unary operators:

 $\begin{tabular}{|c|c|c|c|c|} \hline Strict & distributivity of < and > \hline \\ (\text{ND-} <) & \bigvee_{i < \alpha} < x_i = < \bigvee_{i < \alpha} x_i & (\text{ND-} >) & \bigvee_{i < \alpha} > x_i = > \bigvee_{i < \alpha} x_i \\ \hline \end{array}$ 327 With these axioms, **S** supports inequational reasoning, which represents the 328 semantic refinement relation used to validate program transformations [e.g. 12]. 329 Finally, $Ax_{\mathfrak{s}}$ axiomatises \triangleleft and \triangleright as an *(insertion)-closure pair* [e.g. 2]: 330 Closure pair (Empty) $\triangleleft \triangleright y = y$ (Connect) $\vartriangleright \lhd x \ge x$ 331 They are compatible with the global-lock interpretation: 332 **Empty** $(\triangleleft \triangleright y = y)$. Acquiring and immediately releasing the lock has no effect 333 on the sequence of effects that can occur as a result of arbitrary interleavings. 334 **Connect** ($\triangleright \triangleleft x > x$). Releasing and immediately acquiring the lock only al-335 lows more behaviours, as the environment is not obliged to interleave. 336 To summerise, $Ax_{\mathbf{S}} := Ax_{\mathbf{G}}^{\bullet} \cup Ax_{\mathbf{V}}^{\circ} \cup \{ND \neg \rhd, ND \neg \triangleleft\} \cup \{Empty, Connect\}.$ 337 Example 17. The Σ_{s} -equations appearing below are named after corresponding 338

transformations that may or may not be valid, depending on the setting (e.g. is there concurrency, and under what assumptions), all o-sorted over $\{x : o\}$:

$\lhd L_\ell(\rhd x, \rhd x) = x$	(Irrelevant	Read	Intro &	Elin	1)
$\lhd U_{\ell,b_1} \rhd \lhd U_{\ell,b_2} \rhd x \geq \lhd U_{\ell,b_2}$	$\triangleright x$		(Write	Elin	ı)
			(117	т.,	`

$$\lhd \mathsf{U}_{\ell,b_1} \vartriangleright \lhd \mathsf{U}_{\ell,b_2} \vartriangleright x \leq \lhd \mathsf{U}_{\ell,b_2} \vartriangleright x \tag{Write Intro}$$

Intuitively, Irrelevant Read Intro & Elim should be valid in our setting, as 341 looking a value up is not observable by the environment, and the computation 342 itself discards the value. Write Elim should be valid too, because it is possible 343 that the environment does not look ℓ up at the interference point between the 344 updates on the LHS, covering the behaviour denoted by the RHS. On the other 345 hand, Write Intro should be invalid in our setting because only on the LHS can 346 a concurrently running thread look ℓ up and find b_1 . Formally, we will show **S** 347 does not prove Write Intro in example 25. Here we show **S** proves the other two: 348

$$\begin{array}{c} \lhd \mathsf{L}_{\ell} \left(\rhd x, \rhd x \right) \stackrel{\mathrm{LU}}{=} \lhd \mathsf{L}_{\ell} \left(\mathsf{U}_{\ell,0} \, \mathsf{L}_{\ell} \left(\rhd x, \rhd x \right), \mathsf{U}_{\ell,1} \, \mathsf{L}_{\ell} \left(\rhd x, \rhd x \right) \right) \\ & \stackrel{\mathrm{UL}}{=} \lhd \mathsf{L}_{\ell} \left(\mathsf{U}_{\ell,0} \rhd x, \mathsf{U}_{\ell,1} \rhd x \right) \stackrel{\mathrm{LU}}{=} \lhd \rhd \stackrel{\mathrm{Empty}}{x = x} \\ \lhd \mathsf{U}_{\ell,b_1} \rhd \lhd \mathsf{U}_{\ell,b_2} \rhd \stackrel{x \ge}{x} \ge \lhd \mathsf{U}_{\ell,b_1} \, \mathsf{U}_{\ell,b_2} \rhd x \stackrel{\mathrm{UU}}{=} \lhd \mathsf{U}_{\ell,b_2} \rhd x \end{array}$$

349 4 Representation

339

340

We now establish the representation theorem describing a free **S**-model over any $X \in \mathbf{Set}^{\{\bullet, \circ\}}$. Following Brookes [7], we use sets of traces to denote behaviours.

352 4.1 Sorted traces

A sorted trace starts with a sort (\bullet or \circ) followed by a non-empty sequence of 353 state transitions, and ending in a sorted value. The initial sort in the trace and 354 the initial store in each transition represent assumptions the trace relies on from 355 its concurrent and sequential environment. The final sort and value and the final 356 store in each transition represent guarantees the trace makes to its environment. 357 Formally, a *(state) transition* is a pair $\langle \sigma, \rho \rangle \in \mathbb{S} \times \mathbb{S}$. Let $\xi^? \in (\mathbb{S} \times \mathbb{S})^*$ range 358 over possibly empty sequences of transitions, and $\xi \in (\mathbb{S} \times \mathbb{S})^+$ range over non-359 empty ones. For any set X, define the set of X-valued Brookes traces TX :=360 $(\mathbb{S} \times \mathbb{S})^+ \times X$, also used in Brookes's model (§5). For any family $X \in \mathbf{Set}^{\{\bullet, o\}}$ 361 define the $\{\bullet, \circ\}$ -sorted family **T**X of traces $(\mathbf{T}X)_{\Box} := \mathsf{T} \oint X$. Then, for any 362 sorted family $X \in \mathbf{Set}^{\{\bullet, \circ\}}$, we define the set of *sorted traces over* X by: 363

$$\mathbb{T} X \coloneqq \oint \mathsf{T} X = \{ \bullet, \mathsf{o} \} \times (\mathbb{S} \times \mathbb{S})^+ \times \coprod_{\mathsf{o} \in \{ \bullet, \mathsf{o} \}} X_\mathsf{o}$$

³⁶⁴ A \square -sorted \Diamond -valued trace is one of the form $\square \xi \Diamond x := \langle \square, \xi, \text{in}_{\Diamond} x \rangle$ in the set $\mathbb{T}X$.

Example 18. $\bullet\langle 1, 0\rangle\langle 1, 0\rangle \circ 7 \in \mathbb{T}X$, with $X_{\circ} = \mathbb{N}$, is \bullet -sorted and \circ -valued. \Box

Intuitively, the trace $\Box \xi \diamond x$ models a possible behaviour, or protocol, that a shared-state program phrase under preemptive interleaving concurrency can adhere to, given as a rely/guarantee sequence.

³⁶⁹ Example 19. The behaviour denoted by $\langle 1, 0 \rangle \langle 1, 0 \rangle \langle 1, 0 \rangle \rangle$ relies on the preceding ³⁷⁰ environment for $\frac{1}{1}$ and for the sequential environment to hold access to the store; ³⁷¹ then guarantees $\frac{1}{0}$; then relies on $\frac{1}{1}$; and finally guarantees $\frac{0}{0}$, and returns 7 to ³⁷² the succeeding sequential environment, ceding exclusive store access.

One can make these trace-semantic concepts more formal, for example, when 373 formulating an adequacy proof w.r.t. an operational semantics. We will not define 374 these concepts formally since we will not need the additional level of rigour, for 375 example, because we appeal to the well-established adequacy of Brookes's model. 376 We implicitly understand the exclusive access to the store is ceded (\circ) be-377 tween transitions. For example, for the trace $\langle 1, 1, 0 \rangle \langle 1, 0 \rangle \circ 7$, we could write 378 $(1, 1, 1) \circ (1, 0) \circ 7$ for emphasis. A hypothetical $(1, 1, 0) \circ (1, 0) \circ 7$ would denote 379 an impossible behaviour, making intermediate sorts redundant. 380

One of Brookes's innovations is that sets of traces should be closed under what we now call *(trace)* deductions. Specifically, Brookes identified two such deductions, given as binary relations called stutter (\xrightarrow{st}) and mumble (\xrightarrow{mu}) , defined in such a way that if the program phrase can adhere to the source protocol (left of arrow), then it can adhere to the target protocol (right of arrow).

We define these deductions in our two-sorted setting. For convenience, we write $\Box \xi_1^2 \circ \xi_2^2 \diamond x$ for the trace $\Box \xi_1^2 \xi_2^2 \diamond x$ in which, intuitively, the lock is ceded (o) at the marked spot. Formally, we require that both (a) if ξ_1^2 is empty, then $\Box = 0$; and (b) if ξ_2^2 is empty, then $\diamond = 0$. In particular, the requirement holds when both ξ_1^2 and ξ_2^2 are non-empty, where we implicitly assume the ceded sort between them; and in the case of a 0-sorted 0-valued trace, i.e. $\Box = 0 = \diamond$.

11

Example 20. We have the following valid/invalid notations for $\bullet(1, 1, 0)(1, 0) \circ 7$:

valid: $\bullet\langle_1, 0\rangle \circ\langle_1, 0\rangle \circ 7$ $\bullet\langle_1, 0\rangle \circ 7$ $\bullet\langle_1, 0\rangle \circ 7$ invalid: $\bullet\circ\langle_1, 0\rangle \langle_1, 0\rangle \circ 7$ \Box

³⁹³ We define the following *sorted stutter and mumble deductions*:

$$\Box \xi_1^? \mathsf{o} \xi_2^? \diamond x \xrightarrow{\mathtt{st}} \Box \xi_1^? \langle \sigma, \sigma \rangle \xi_2^? \diamond x \qquad \Box \xi_1^? \langle \sigma, \rho \rangle \langle \rho, \theta \rangle \xi_2^? \diamond x \xrightarrow{\mathtt{mu}} \Box \xi_1^? \langle \sigma, \theta \rangle \xi_2^? \diamond x$$

The condition on stutter's source rules out deductions which implicitly cede access to the store to the concurrent environment at the ends of the trace. We will compare these deductions to Brookes's in §5.

³⁹⁷ Example 21. These deductions are valid, highlighting the change to the trace:

³⁹⁸ However, thanks to the condition on stutter's source, this deduction is invalid:

 $\bullet \langle \begin{smallmatrix} 1 \\ 1 \\ 1 \\ 0 \rangle \langle \begin{smallmatrix} 1 \\ 1 \\ 1 \\ 0 \rangle \rangle 07 \xrightarrow{\text{st}} \bullet \langle \begin{smallmatrix} 0 \\ 1 \\ 1 \\ 1 \\ 1 \rangle \langle \begin{smallmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 0 \rangle \langle \begin{smallmatrix} 1 \\ 1 \\ 1 \\ 0 \rangle \rangle 07$

The source protocol relies on the preceding sequential environment for $\frac{1}{1}$. We prohibit relaxing the protocol to rely on the concurrent environment for it. \Box

⁴⁰¹ The stutter and mumble deductions follow the rely/guarantee intuition:

402 **Stuttering** $(\Box \xi_1^? \circ \xi_2^? \diamond x \xrightarrow{st} \Box \xi_1^? \langle \sigma, \sigma \rangle \xi_2^? \diamond x)$ means a thread-pool also obeys the 403 protocol that guarantees a state σ by relying on its environment for σ . 404 **Mumbling** $(\Box \xi_1^? \langle \sigma, \rho \rangle \langle \rho, \theta \rangle \xi_2^? \diamond x \xrightarrow{mu} \Box \xi_1^? \langle \sigma, \theta \rangle \xi_2^? \diamond x)$ means a thread-pool which

404 **Mumbling** $(\Box \xi_1^? \langle \sigma, \rho \rangle \langle \rho, \theta \rangle \xi_2^? \Diamond x \xrightarrow{\mathrm{mu}} \Box \xi_1^? \langle \sigma, \theta \rangle \xi_2^? \Diamond x)$ means a thread-pool which 405 guarantees the store ρ it later relies on also obeys the protocol in which we 406 exclude the environment's access to the store ρ at that point.

Sets of traces represent a non-deterministic choice between the behaviours 407 that a program phrase may exhibit. For such a set K, define its *closure* under 408 trace deduction K^{\dagger} as the least set K' such that: $K \subseteq K'$; and if $\tau_1 \in K'$ 409 and $\tau_1 \xrightarrow{\mathbf{x}} \tau_2$ for $\mathbf{x} \in \{\mathtt{st}, \mathtt{mu}\}$, then $\tau_2 \in K'$. According to the rely/guarantee 410 intuition above, a program phrase that is compatible with a set of traces is also 411 compatible with its closure. We therefore represent program phrases as *closed* 412 sets, i.e. sets K such that $K = K^{\dagger}$. The closure K^{\dagger} of a countable K is countably 413 infinite—by stuttering indefinitely—unless K is a finite set of single-transition 414 •-sorted •-valued traces, in which case K is already closed. 415

For a set of traces U and sort $\square \in \{\bullet, \mathsf{o}\}$, define a $\{\bullet, \mathsf{o}\}$ -sorted family $\mathbf{P}^{\aleph_0}(U)$ by taking its \square component to be the set $\mathbf{P}_{\square}^{\aleph_0}(U)$ of countable subsets of U whose elements are all \square -sorted. Similarly, define $\mathbf{P}_{\square}^{\dagger}(U) \subseteq \mathbf{P}_{\square}^{\aleph_0}(U)$ to be the set of *closed* countable subsets of U whose elements are all \square -sorted.

 $_{420}$ The *prefixing* function adds the given transition to each \bullet -sorted trace:

 $(\sigma,\rho):\mathbf{P}^{\aleph_0}_{\bullet}(\mathbb{T}\boldsymbol{X})\to\mathbf{P}^{\aleph_0}_{\bullet}(\mathbb{T}\boldsymbol{X})\quad (\sigma,\rho)\,K\coloneqq\left\{\bullet\langle\sigma,\theta\rangle\xi^?\,\Diamond x\;\big|\;\bullet\langle\rho,\theta\rangle\xi^?\,\Diamond x\in K\right\}$

It lifts to closed sets, i.e. $K \in \mathbf{P}^{\dagger}_{\bullet}(\mathbb{T}X)$ implies that $(\sigma, \rho) K \in \mathbf{P}^{\dagger}_{\bullet}(\mathbb{T}X)$.

13

422 4.2 Representation theorem

⁴²³ For $X \in \mathbf{Set}^{\{\bullet, \circ\}}$, define the $\Sigma_{\mathfrak{S}}$ -algebra of X-valued closed trace-sets $\mathbf{R}X$ as:

$$\begin{split} \underline{\mathbf{R}}_{\mathbf{X}_{\Box}} &\coloneqq \mathbf{P}_{\Box}^{\dagger} \left(\mathbb{T} \mathbf{X} \right) & [\![\mathbf{U}_{\ell,b}]\!]_{\mathrm{op}} K \coloneqq \bigcup_{\sigma \in \mathbb{S}} \left(\sigma, \sigma[\ell \mapsto b] \right) K \\ [\![\mathbf{V}_{i < \alpha}]\!]_{\mathrm{op}} K_{i} &\coloneqq \bigcup_{i < \alpha} K_{i} & [\![\mathbf{L}_{\ell}]\!]_{\mathrm{op}} (K_{0}, K_{1}) \coloneqq \bigcup_{\sigma \in \mathbb{S}} \left(\sigma, \sigma \right) K_{\sigma_{\ell}} \\ [\![\mathbf{d}]\!]_{\mathrm{op}} K &\coloneqq \left\{ \mathbf{o} \xi \Diamond x \mid \mathbf{o} \xi \Diamond x \in K \right\}^{\dagger} & [\![\mathbf{b}]\!]_{\mathrm{op}} K \coloneqq \left\{ \mathbf{o} \langle \sigma, \sigma \rangle \xi \Diamond x \mid \sigma \in \mathbb{S}, \mathbf{o} \xi \Diamond x \in K \right\}^{\dagger} \end{split}$$

⁴²⁴ Additionally, define return : $X \to \underline{\mathbf{R}X}$ by return $x := \{\Box(\sigma, \sigma) \Box x \mid \sigma \in \mathbb{S}\}^{\dagger}$.

The rest of this section establishes that the algebra $\langle \mathbf{R} \mathbf{X}, \operatorname{return} \rangle$ over \mathbf{X} is a free \mathbb{S} -model over \mathbf{X} . A key ingredient is *reification*: for any $\{\bullet, \mathsf{o}\}$ -sorted family \mathbf{X} , we define a sorted-function reify: $\mathbf{P}^{\aleph_0}(\mathbb{T} \mathbf{X}) \to \operatorname{Term}^{\Sigma_{\mathfrak{S}}} \mathbf{X}$, choosing a representative term $t_2 := \operatorname{reify} [\![\mathbf{X} \vdash t_1]\!]_{\operatorname{term}}$ such that $\mathbf{X} \vdash_{\mathfrak{S}} t_1 = t_2$. This use of countable choice is inessential, the mere existence of the defining term t_2 suffices. First define for any $\ell \in \mathbb{L}$ and $b \in \mathbb{B}$ the *cell assertion* term $x : \bullet \vdash_{\Sigma_{\mathfrak{S}}} \mathsf{A}_{\ell, b} x : \bullet$ that looks ℓ up and only continues if it holds b:

$$x: \bullet \vdash_{\Sigma_{\$}} \mathsf{A}_{\ell, \mathsf{o}} \, x \coloneqq \mathsf{L}_{\ell}(x, \bot): \bullet \qquad x: \bullet \vdash_{\Sigma_{\$}} \mathsf{A}_{\ell, \mathsf{1}} \, x \coloneqq \mathsf{L}_{\ell}(\bot, x): \bullet$$

⁴³² Next, for any $\sigma, \rho \in \mathbb{S}$ define the open transition $x : \bullet \vdash_{\Sigma_{\mathfrak{S}}} \{\sigma, \rho\} x : \bullet$, a ⁴³³ term that asserts the state is σ , then updates the state to ρ , and returns x:

$$x: \bullet \vdash_{\Sigma_{\mathfrak{F}}} \{\sigma, \rho\} \ x \coloneqq \mathsf{A}_{\mathtt{l}_1, \sigma_{\mathtt{l}_1}} \dots \mathsf{A}_{\mathtt{l}_n, \sigma_{\mathtt{l}_n}} \ \mathsf{U}_{\mathtt{l}_1, \rho_{\mathtt{l}_1}} \dots \mathsf{U}_{\mathtt{l}_n, \rho_n} \ x: \bullet \quad (\mathbb{L} = \{\mathtt{l}_1, \dots, \mathtt{l}_n\})$$

⁴³⁴ Define the $\Sigma_{\mathfrak{S}}$ -term reifying a trace $x : \diamond \vdash_{\Sigma_{\mathfrak{S}}} \underline{\Box} \xi \diamond x : \Box$ by sequencing open ⁴³⁵ transition as they are in ξ , separated by $\triangleright \lhd$; and delimited by \lhd on the left if ⁴³⁶ $\Box = \circ$ and by \triangleright on the right if $\diamond = \circ$.

$$\text{437} \quad Example \ 22. \ x: \mathsf{o} \vdash_{\Sigma_{\mathfrak{S}}} \underline{\bullet}\langle \sigma, \rho \rangle \langle \sigma', \rho' \rangle \mathbf{o} x := \{\sigma, \rho\} \vartriangleright \lhd \{\sigma', \rho'\} \vartriangleright x: \bullet \qquad \Box$$

438 Trace deductions are sound w.r.t. this encoding, in the following sense:

⁴³⁹ **Proposition 23.** Assume that τ_1 and τ_2 are \square -sorted traces over $\{x : \emptyset\}$, such ⁴⁴⁰ that $\tau_1 \xrightarrow{x} \tau_2$ for $x \in \{\mathtt{st}, \mathtt{mu}\}$. Then $\{x : \emptyset\} \vdash_{\Sigma_{\mathfrak{K}}} \tau_1 \geq \tau_2 : \square$.

Finally, we reify a trace set by reifying its traces in a chosen enumeration:

$$\operatorname{reify}: \mathbf{P}^{\aleph_0}(\mathbb{T}\boldsymbol{X}) \to \operatorname{Term}^{\Sigma_{\mathfrak{F}}}\boldsymbol{X} \qquad \operatorname{reify}_{\Box} K \coloneqq \left(\boldsymbol{X} \vdash_{\Sigma_{\mathfrak{F}}} \bigvee_{\tau \in K^{\underline{\tau}}} \colon \Box\right)$$

⁴⁴² By proposition 23, closure preserves reification: $X \vdash_{\mathfrak{S}} \operatorname{reify}_{\square} K = \operatorname{reify}_{\square} K^{\dagger} : \square$.

443 With reification defined, we are ready to state the representation theorem.

Theorem 24 (S-representation). The pair $\langle \mathbf{R} \mathbf{X}, \operatorname{return} \rangle$ is a free S-model over \mathbf{X} . Its representation sends environments $e : \mathbf{X} \to \underline{\mathbf{A}}$ to S-homomorphisms $e^{\#} : \mathbf{R} \mathbf{X} \to \mathbf{A}$ by $e_{\square}^{\#} K := \mathbf{R} \mathbf{X} [\operatorname{reify}_{\square} K]_{\operatorname{term}} e$. Moreover, for $\mathbf{A} = \mathbf{R} \mathbf{Y}$ we have:

$${}^{_{447}} \quad e_{\square}^{\#}K = \left\{ \Box\xi_1\xi_2 \otimes y \ \middle| \begin{array}{c} \Box\xi_1 \circ x \in K, \\ \circ\xi_2 \otimes y \in e_{\diamond}x \end{array} \right\}' \cup \left\{ \Box\xi_1 \langle \sigma, \theta \rangle \xi_2 \otimes y \ \middle| \begin{array}{c} \Box\xi_1 \langle \sigma, \rho \rangle \bullet x \in K, \\ \bullet \langle \rho, \theta \rangle \xi_2 \otimes y \in e_{\diamond}x \end{array} \right\}'$$

448 Example 25. The model $\mathbf{R} \{x : 0\}$ invalidates Write Intro:

 $\mathbf{R} \{ x: \mathbf{o} \} \llbracket \triangleleft \mathsf{U}_{\ell, b_1} \rhd \triangleleft \mathsf{U}_{\ell, b_2} \rhd x \rrbracket_{\text{term}} \text{return} \neq \mathbf{R} \{ x: \mathbf{o} \} \llbracket \triangleleft \mathsf{U}_{\ell, b_2} \rhd x \rrbracket_{\text{term}} \text{return}$

Every trace in the right-hand set has at most one state-changing transition. The left-hand set has traces with two. Therefore, **S** does not prove Write Intro. \Box

451 5 Recovering Brookes's model

The theory **S** recovers Brookes's model (§5.1). We recover it twice, using different strategies that offer different perspectives. First, we transform the monad induced by the representation of §4.2 along a right adjoint $\mathbf{Set}^{\{\bullet, \circ\}} \to \mathbf{Set}$ (§5.2). Then, we define an embedding translation from a single-sorted theory of transitions into **S** (§5.4), corresponding to Brookes's await construct (§5.3).

457 5.1 Brookes's model

We designed our notions of traces, deduction, etc. from §4.1 based on the following model of Brookes [7]. For any set $X \in$ **Set**, recall the set of Brookes traces $TX := (S \times S)^+ \times X$ from §4.1. Writing ξx for $\langle \xi, x \rangle$, Brookes's stutter and mumble trace deductions are:

$$\xi_1^? \xi_2^? x \xrightarrow{\mathtt{st}} \xi_1^? \langle \sigma, \sigma \rangle \xi_2^? x \qquad \xi_1^? \langle \sigma, \rho \rangle \langle \rho, \theta \rangle \xi_2^? x \xrightarrow{\mathtt{mu}} \xi_1^? \langle \sigma, \theta \rangle \xi_2^? x$$

462 We reuse the notation $(-)^{\dagger}$ for closure under these deductions.

The difference between Brookes's and our multi-sorted deuctions is the maintenance of the sort in the ends of the trace. In particular, Brookes's stutter does not need to assume the 'cede' sort (o) at the stuttering position in the source. In Brookes's model, the environment may always interleave in either end.

⁴⁶⁷ Brookes's semantic domain $BX := \mathbf{P}^{\dagger}(\mathsf{T}X)$ forms a monad. The monadic ⁴⁶⁸ unit is return : $X \to BX$, return $x := \{\langle \sigma, \sigma \rangle x \mid \sigma \in \mathbb{S}\}^{\dagger}$. The Kleisli extension ⁴⁶⁹ $e^{\#} : BX \to BY$ of every $e : X \to BY$ is $e^{\#}K := \{\xi_1\xi_2y \mid \xi_1x \in K, \xi_2y \in ex\}^{\dagger}$. It ⁴⁷⁰ interprets memory accesses, dereferencing $(\ell!)$ and mutation $(\ell := b)$, as follows:

$$\llbracket \ell ! \rrbracket : \mathbb{1} \xrightarrow{\{ \langle \sigma, \sigma \rangle \sigma \ell \mid \sigma \in \mathbb{S} \}^{\dagger}} B \mathbb{B} \quad \llbracket \ell := b \rrbracket : \mathbb{1} \xrightarrow{\{ \langle \sigma, \sigma [\ell \mapsto b] \rangle \langle \rangle \mid \sigma \in \mathbb{S} \}^{\dagger}} B \mathbb{I}$$

⁴⁷¹ These generic effects [34] correspond to these monadic algebraic operations:

$$\begin{split} \llbracket \mathsf{R}_{\ell} \rrbracket &: (BX)^2 \to BX & \llbracket \mathsf{R}_{\ell} \rrbracket (K_0, K_1) \coloneqq \{ \langle \sigma, \sigma \rangle \xi x \mid \sigma \in \mathbb{S}, \xi x \in K_{\sigma\ell} \}^{!} \\ \llbracket \mathsf{W}_{\ell, b} \rrbracket : BX & \to BX & \llbracket \mathsf{W}_{\ell, b} \rrbracket K \coloneqq \{ \langle \sigma, \sigma[\ell \mapsto b] \rangle \xi x \mid \sigma \in \mathbb{S}, \xi x \in K \}^{\dagger} \end{split}$$

472 5.2 Recovery via an adjunction

⁴⁷³ In Brookes's model, yielding to the concurrent environment is implicit, and ⁴⁷⁴ always allowed. From our two-sorted point-of-view, we expect the traces in ⁴⁷⁵ Brookes's to represent o-sorted o-valued traces.

There is an abstract construction that recovers the monad and its operations in §5.2 from our $\{\bullet, \circ\}$ -sorted model. The functor $(-)_{\circ} : \mathbf{Set}^{\{\bullet, \circ\}} \to \mathbf{Set}$ has a left-adjoint $(-)^{\circ} : \mathbf{Set} \to \mathbf{Set}^{\{\bullet, \circ\}}$. This functor sends each set X to the $\{\bullet, \circ\}$ -family $X^{\circ} := \{x : \circ \mid x \in X\}$, using the set-like notation for families we introduced in §2.1. Monads transform along adjoints, and transforming the monad obtained standardly from the representation of §4.2 along the adjunction above

15

results in Brookes's model. Explicitly, denoting $B_{o}X := \underline{\mathbf{R}}X_{o}^{\circ} = \mathbf{P}_{o}^{\dagger}(\mathbb{T}X^{\circ})$, the resulting monad over **Set** is $\langle B_{o}, \operatorname{return}_{o}, (-)_{o}^{\#} \rangle$. This monad is isomorphic to Brookes's $\langle B, \operatorname{return}, (-)^{\#} \rangle$ above by way of removing \circ from both ends of every trace. Thus, the Brookes model amounts to the free **S**-model from §4.2 transformed along the adjunction $(-)^{\circ} \dashv (-)_{\circ}$. The monad \mathbf{R} supports the following generic effects. The adjunction transforms them, via its natural bijection on homsets, into Brookes's generic effects for memory access:

$$\llbracket \ell ! \rrbracket : \mathbb{1}^{\circ} \xrightarrow{\llbracket \lhd \mathsf{L}_{\ell}(\rhd 0, \rhd 1) \rrbracket} \mathbf{R} \mathbb{B}^{\circ} \qquad \llbracket \ell := b \rrbracket : \mathbb{1}^{\circ} \xrightarrow{\llbracket \lhd \mathsf{U}_{\ell, b} \rhd \langle \rangle \rrbracket} \mathbf{R} \mathbb{1}^{\circ}$$

489 5.3 The single-sorted theory of transitions

⁴⁹⁰ There is a more direct, single-sorted presentation B for Brookes's model. It uses ⁴⁹¹ transitions as operators rather than lookup and update operators. The signature ⁴⁹² $\Sigma_{\rm B}$ consists of countable-join semilattice $\Sigma_{\rm V}$ and a unary operator $\langle \sigma, \rho \rangle$ for ⁴⁹³ every $\sigma, \rho \in \mathbb{S}$. The axioms $Ax_{\rm B}$ consists of countable-join semilattice $Ax_{\rm V}$, ⁴⁹⁴ commutativity axioms (ND-B) $\langle \sigma, \rho \rangle \bigvee_{i < \alpha} x_i = \bigvee_{i < \alpha} \langle \sigma, \rho \rangle x_i$, and:

$$\begin{array}{c|c} & \text{Trace closure} \\ \hline (\text{M}) \ \langle \sigma, \rho \rangle \langle \rho, \theta \rangle x \geq \langle \sigma, \theta \rangle x & \text{(S)} \ x \geq \langle \sigma, \sigma \rangle x & \text{(H)} \ \bigvee_{\sigma \in \mathbb{S}} \langle \sigma, \sigma \rangle x \geq x \end{array}$$

495

The first two axiom schemes are algebraic counterparts to mumble and stutter. These alone do not recover Brookes's model—the representation theorem for the theory without the (H) axioms includes potentially-empty traces. The axiom (H) fails in this model, but holds in Brookes's. In the representation theorem for B it is tempting to require of sets of traces K to be closure under, in addition to Brookes's mumble and stutter trace deductions, the following closure condition:

$$\frac{\forall \sigma.\,\xi_1^?\langle\sigma,\sigma\rangle\xi_2^?x\in K}{\xi_1^?\xi_2^?x\in K}(\mathsf{hush})$$

The closure rule hush is admissible for trace-deduction closed K, due to the nonemptiness of the traces and closure under mumble. Indeed, either ξ_1^2 or ξ_2^2 must be non-empty for the rule to apply. Take σ to match an adjacent transition, and apply the mumble closure rule to obtain the required consequence. This nuanced observation would be hard to notice without this algebraic analysis.

To conclude, we formulate the representation theorem for B. Let $X \in$ **Set**. Define the Σ_{B} -algebra **B**X with carrier **B**X := **P**[†](**T**X) and interpretations:

$$\mathbf{B}X[\![\mathsf{V}_{i<\alpha}]\!]_{\mathrm{op}}K \coloneqq \bigcup_{i<\alpha}K_i \qquad \mathbf{B}X[\![\langle\sigma,\rho\rangle]\!]_{\mathrm{op}}K \coloneqq \{\langle\sigma,\rho\rangle\tau \mid \tau \in K\}^{\dagger}$$

Additionally, define return : $X \to \underline{\mathbf{B}} X$ by return $x := \lambda x$. $\{\langle \sigma, \sigma \rangle x \mid \sigma \in \mathbb{S}\}^{\dagger}$.

To prove that this is a free B-model, we use reification as in §4.2, though here reification is more straightforward. A trace is reified as itself, and sets of traces use countable-join as before: reify $K := (\mathbf{X} \vdash_{\Sigma_{\mathsf{B}}} \bigvee_{\tau \in K} \underline{\tau} : \star)$. The monad obtained from the next proposition is Brookes's model:

Proposition 26. The pair $\langle \mathbf{B}X, \operatorname{return} \rangle$ is a free B-model over X, for which the representation sends $e: X \to \underline{\mathbf{A}}$ to $e^{\#}: \mathbf{B}X \to \mathbf{A}$ by $e_{\square}^{\#}K := \mathbf{B}X[\operatorname{reify}_{\square}K]_{\operatorname{term}}e$.

516 5.4 Translations and equivalences

We will need the following notions for relating presentations. Consider a map between two sort sets $\epsilon : \mathbf{sort}_1 \to \mathbf{sort}_2$. It lifts to $\epsilon : \mathbf{Set}^{\mathbf{sort}_2} \to \mathbf{Set}^{\mathbf{sort}_1}$ by precomposition: $(\epsilon \mathbf{Y})_{\square} := \mathbf{Y}_{\epsilon\square}$. It forms the object part of a geometric morphism between (pre)sheaf toposes, i.e., it has left and right adjoints. The left adjoint $\epsilon^* : \mathbf{Set}^{\mathbf{sort}_1} \to \mathbf{Set}^{\mathbf{sort}_2}$ is in this case $(\epsilon^* \mathbf{X})_{\diamond} := \prod_{\epsilon\square=\diamond} \mathbf{X}_{\square}$. When ϵ is injective, the left adjoint is given by the simpler formula $\epsilon^* \mathbf{X} := \{x : \epsilon\square \mid x \in \mathbf{X}_{\square}\}$.

Example 27. The geometric morphism for the map $\star \mapsto \mathbf{o} : \{\star\} \mapsto \{\bullet, \mathbf{o}\}$ is the forgetful functor $(-)_{\mathbf{o}} : \mathbf{Set}^{\{\bullet, \mathbf{o}\}} \to \mathbf{Set}^{\{\star\}} \cong \mathbf{Set}$. As we saw in §5.2, its left adjoint is $(-)^{\mathbf{o}} : \mathbf{Set}^{\{\star\}} \to \mathbf{Set}^{\{\bullet, \mathbf{o}\}}$.

Let Σ_1 and Σ_2 be signatures and $\epsilon : \operatorname{sort}_{\Sigma_1} \to \operatorname{sort}_{\Sigma_2}$ a map between their sort sets. A translation of signatures $\mathbf{E} : \Sigma_1 \to \Sigma_2$ along ϵ is an assignment, to each $(O : \Box \langle \phi_i \rangle_{i < \alpha}) \in \Sigma_1$, of a term $\mathbf{E}O \in \operatorname{Term}_{\epsilon \Box}^{\Sigma_2} \{x_i : \epsilon \phi_i \mid i < \alpha\}$. Such a translation yields a functor $\mathbf{E}_{\operatorname{tln}} : \operatorname{Alg}\Sigma_2 \to \operatorname{Alg}\Sigma_1$, mapping a Σ_2 -algebra \mathbf{B} to:

$$\underline{\mathbf{E}_{\mathrm{tln}}\mathbf{B}} \coloneqq \epsilon \underline{\mathbf{B}} \qquad \mathbf{E}_{\mathrm{tln}}\mathbf{B} \left[\!\left[O : \mathbf{\Box} \langle \diamondsuit_i \rangle_{i < \alpha} \right]\!\right]_{\mathrm{op}} \langle b_i \rangle \coloneqq \mathbf{B} \left[\!\left[\mathbf{E}O\right]\!\right]_{\mathrm{term}} \langle x_i \mapsto b_i \rangle_{i < \alpha}$$

For a given family $\mathbf{Y} \in \mathbf{Set}^{\mathbf{sort}_{\Sigma_2}}$, such a translation therefore extends uniquely to a Σ_1 -homomorphism $(\mathbf{E}_{\mathrm{tln}})_{\mathbf{Y}} : F_{\Sigma_1} \epsilon \mathbf{Y} \to \mathbf{E}_{\mathrm{tln}} F_{\Sigma_2} \mathbf{Y}$.

Example 28. We have a translation $\mathbf{E} : \Sigma_{\mathsf{G}} \to \Sigma_{\mathsf{S}}$ along $\star \mapsto \bullet : \{\star\} \to \{\bullet, \mathsf{o}\}$ that translates the Σ_{G} -operators using their respective copies in the \bullet sort:

$$\begin{array}{ll} \mathbf{E}(\bigvee_{\alpha}:\alpha) \coloneqq (\{x_{i}:\bullet \mid i < \alpha\} \vdash_{\Sigma_{\mathfrak{S}}} \bigvee_{i < \alpha} x_{i} : \bullet) \\ \mathbf{E}(\mathsf{L}_{\ell}:\mathbf{2}) \coloneqq (\{x_{0}, x_{1}:\bullet\} \quad \vdash_{\Sigma_{\mathfrak{S}}} \mathsf{L}_{\ell}(x_{0}, x_{1}) : \bullet) \\ \mathbf{E}(\mathsf{U}_{\ell,b}:\mathbf{1}) \coloneqq (\{x_{0}:\bullet\} \quad \vdash_{\Sigma_{\mathfrak{S}}} \mathsf{U}_{\ell,b} x_{0} : \bullet) \end{array}$$

A translation of *presentations* $\mathbf{E} : \mathfrak{p}_1 \rightarrow \mathfrak{p}_2$ along ϵ is a translation of their signatures along ϵ that, moreover, preserves the provability of axioms:

$$(\boldsymbol{X}\vdash_{\Sigma_{\mathfrak{p}_1}} t_1=t_2: \square)\in \mathrm{Ax}_{\mathfrak{p}_1}\implies \epsilon^*\boldsymbol{X}\vdash_{\mathfrak{p}_2} \mathbf{E}_{\mathrm{tln}}t_1=\mathbf{E}_{\mathrm{tln}}t_2: \epsilon\square$$

Example 29. The translation of global state into shared state from example 28 is a translation of presentations $\mathbf{E} : \mathbf{G} \rightarrow \mathbf{S}$.

Translations along composable sort maps compose via substitution, and a translation $\mathbf{E} : \mathfrak{p} \to \mathfrak{p}$ along $\mathrm{id}_{\Sigma_{\mathfrak{p}}}$ is an *identity* translation when, for all terms $t \in \mathrm{Term}_{\square}^{\Sigma_{\mathfrak{p}}} \mathbf{X}$, we have $\mathbf{X} \vdash_{\mathfrak{p}} \mathbf{E}_{\mathrm{tln}} t = t : \square$. A translation $\mathbf{E} : \mathfrak{p}_1 \to \mathfrak{p}_2$ along ϵ is an *equivalence* if ϵ is a bijection, and there exists an embedding $\mathbf{E}^{-1} : \mathfrak{p}_2 \to \mathfrak{p}_1$ along ϵ^{-1} , such that $\mathbf{E} \circ \mathbf{E}^{-1}$ and $\mathbf{E}^{-1} \circ \mathbf{E}$ are identity translations. We then write $\mathfrak{p}_1 \simeq \mathfrak{p}_2$ and say that the presentations are *equivalent*. Two multi-sorted theories are equivalent iff their associated free-model monads are isomorphic.

545 5.5 Translation through the two-sorted theory of transitions

We define a two-sorted presentation Tgs of the *open* transitions $\{\sigma, \rho\}$ as sequential operators. The signature Σ_{Tgs} has countable-joins and a unary operator (σ, ρ) for $\sigma, \rho \in \mathbb{S}$. The axioms $\operatorname{Ax}_{\mathsf{Tgs}}$ consist of countable-join semilattice $\operatorname{Ax}_{\mathsf{V}}$, strict distributivity axioms (ND-T) $(\sigma, \rho) \bigvee_{i < \alpha} x_i = \bigvee_{i < \alpha} (\sigma, \rho) x_i$, and:

Open transition axioms	$(\operatorname{Seq}^{=})$ (σ, ρ) (ρ, θ) $x = (\sigma, \theta) x$	
(HS) $x = \bigvee_{\sigma \in \mathbb{S}} (\sigma, \sigma) x$	(Seq^{\neq}) (σ, ρ) (μ, θ) $x = \bot$	$\rho \neq \mu$

550

⁵⁵¹ Define the translation $\mathbf{E}_{\mathsf{G}} : \mathsf{Tgs} \to \mathsf{G}$ by interpreting transitions as the open ⁵⁵² transitions from §4.2: $\mathbf{E}_{\mathsf{Gtln}}(\sigma, \rho) := \{\sigma, \rho\} x_0$. Conversely, $\mathbf{E}_{\mathsf{Tgs}} : \mathsf{G} \to \mathsf{Tgs}$ by ⁵⁵³ interpreting lookup and update as follows, similar to the representation of §4.2:

$$\mathbf{E}_{\mathsf{Tgs}_{\mathrm{tln}}}\mathsf{U}_{\ell,b} \coloneqq \bigvee_{\sigma \in \mathbb{S}} (\sigma, \sigma[\ell \mapsto b]) \ x_0 \qquad \mathbf{E}_{\mathsf{Tgs}_{\mathrm{tln}}}\mathsf{L}_{\ell} \coloneqq \bigvee_{\sigma \in \mathbb{S}} (\sigma, \sigma) \ x_{\sigma_{\ell}}$$

 $_{554}$ These witness an equivalence: $G\simeq Tgs.$

This equivalence lets us use Tgs instead of G in the atomic block layer of S . In detail, the presentation Tr of the two-sorted theory of transitions is given by $\operatorname{Ax}_{\mathsf{Tr}} := [\operatorname{Ax}^{\bullet}_{\mathsf{Tgs}}] \cup \operatorname{Ax}^{\circ}_{\mathsf{V}} \cup \{\operatorname{ND-} \rhd, \operatorname{ND-} \triangleleft\} \cup \{\operatorname{Empty}, \operatorname{Connect}\}$. Extending the translations $\mathbf{E}_{\mathsf{Tgs}}$ and \mathbf{E}_{G} to all of the operators gives an equivalence $\mathsf{Tr} \simeq \mathsf{S}$, and so they induce the same monad, and recover Brookes's model.

⁵⁶⁰ Define the translation $\mathbf{E} : \mathbf{B} \rightarrow \mathsf{Tr}$ along $\star \mapsto \mathbf{o}$ by sending transitions to their ⁵⁶¹ delimited open counterparts: $\mathbf{E}_{tln} \langle \sigma, \rho \rangle := \triangleleft (\sigma, \rho) \triangleright x_0$. By post-composition ⁵⁶² with the above equivalence, the single-sorted theory of transitions translate to ⁵⁶³ shared state $\mathbf{B} \rightarrow \mathbf{S}$. Brookes's model, being a free B-model, is thus the o-sorted ⁵⁶⁴ fragment of \mathbf{S} over o-variables, formally.

⁵⁶⁵ 6 Conclusion and further work

We presented an equational theory for shared state (\mathbf{S}) . It separates reasoning 566 into two layers. In the held layer (\bullet) , we prohibit the concurrent environment 567 from accessing memory, and we can reason about memory accesses by a pool 568 of threads sequentially. In the ceded layer (o), the concurrent environment may 569 interleave, but memory access is forbidden. We also presented theories of tran-570 sitions (Tr and Tgs) and formally related them to the shared state theory. One 571 of these theories (Tr) is a single-sorted theory that recovers Brookes's model. 572 We find this theory unsatisfying for a conceptual and a technical reason. Con-573 ceptually, it is a theory of Brookes's await construct, which we find unnatural. 574 Technically, Tr does not admit global state as an explicit component of the the-575 ory. We believe understanding how global state fits as a component will inform 576 modelling other effects in the concurrent setting. The theory of shared state ad-577 dresses these concerns. On the one hand, it admits the global state theory as-578 is, and axiomatizes the interleaving-enabling/disabling operators $(\triangleleft \triangleright)$ without 579 explicit interaction with global state. On the other hand, this theory recovers 580

⁵⁸¹ Brookes's model precisely in a principled manner: by transforming a monad and ⁵⁸² its operations along an adjunction, and through algebraic translations.

Our theory uses countable-join semilattices. In the resulting—Brookes's-583 model, they can express iteration (i.e. while-loops). The same model admits 584 first-order recursion, i.e. least-fixpoints of mutually-defined first-order functions, 585 using the ω -complete partial order structure of the refinement order and the 586 Scott-continuity of the semantics. We can support higher-order recursion by 587 recourse to domain-theory, generalising algebraic theories using order-enriched 588 theories. There are several standard variants, each with subtle logical trade-589 offs [32]. We can also restrict the semantics to terminating languages by using 590 finite-join semilattice instead of countable joins. The resulting representation 591 theorem then uses finitely-generated closed subsets. 592

We want to analyse Brookes's parallel composition operator algebraically. Brookes composed programs in parallel by interleaving traces from each thread. Initial results show we can define Brookes's parallel composition by simultaneous induction over terms. However, we would like to provide a more abstract account, by recourse to the universal property of free models. This abstraction may expose special properties of global state, or lead to general parallel composition operation satisfying the expected laws of concurrent programming [15, 29, 37].

We want to model more effects similarly, within this modular multi-sorted algebraic framework. These effects include: more advanced notions of state, such as dynamic allocation [20], higher-order memory cells [26, 39], and weak memory [13]; control-flow effects such as exceptions and effect handlers [4]; and probabilistic programming with shared state [24].

Our two sorts limit access to the whole store. We would like to explore limiting access in finer granularity, and per-location in the first instance. In this direction, the theory has: sorts for every finite subset $s \subseteq \mathbb{L}$ of locations; and operators:

$$\lhd_{\ell} : s \setminus \{\ell\} \langle s \cup \{\ell\} \rangle \qquad \vartriangleright_{\ell} : s \cup \{\ell\} \langle s \setminus \{\ell\} \rangle$$

⁶⁰⁸ One needs care in designing the appropriate (in)equations for these operators.

It may be interesting to design programming language constructs that expose the sort discipline in the surface language. It is natural to expose them as locking/unlocking, while tracking the capability to call the lock in typing judgements. This construct explicates regions that rule out data-races with the environment. It seems such typing judgements would rule out deadlocks structurally, and so may limit program expressiveness, or be hard to use. It remains to be seen whether such abstractions are useful.

If the multi-sorted approach does indeed generalise to more sophisticated effects, then it will be instructive to review its assumptions. For example, the strictness axioms impose a partial-correctness discipline: the semantics says nothing about the effect a diverging program has on its memory. Relaxing or removing strictness may give a model that allows us to reason about diverging programs. In conclusion, our two-sorted decomposition of Brookes's seminal model provides a new insights into its assumptions and components, and opens up new

research directions for modelling more advanced programming language features involving concurrent shared state.

758 A No-go results

We can present Brookes's model using a single-sorted presentation $(\S5.3)$. How-759 ever, we found this presentation unsatisfactory, and so propose a two-sorted 760 account. Our use of the two-sorted approach follows a relatively thorough inves-761 tigation into alternative single-sorted approaches, and we can provide some crisp 762 results that certain single-sorted approaches fail. These no-go results, together 763 with the perspectives on future work the two-sorted decomposition suggests (§6), 764 are evidence for the merit of our two-sorted approach. They may also inform fu-765 ture search for a single-sorted presentation that we have overlooked. 766

Single-sorted transitions present Brookes's model in terms of the await construct. This presentation highlights await's importance for reasoning in Brookes's
model and why await is a key ingredient in Brookes's full abstraction result.
Without await, Brookes's model is not fully abstract at 1st-order:

No-go 1 (Svyatlovskiy et al. [40]). Brookes's model is not fully-abstract
 w.r.t. the operational semantics in which differentiating contexts can only read
 and mutate single memory cells atomically.

Moreover, every single-sorted presentation of Brookes's model must involve operators other than the interpretation of read and write, considered as generic effects [34]. Formally, given a family of algebraic operations and a monad, we can construct the sub-monad generated by a set of operations [19, 21, 22].

No-go 2. The sub-monad generated by the semantics of read and write, and by
 union, differs from the Brookes model.

⁷⁸⁰ *Proof.* The trace-sets generated by read and write always contain a trace in ⁷⁸¹ which at most one cell changes within each transition. Brookes's model includes ⁷⁸² other subsets, definable via the **await** construct. \Box

The traces in Brookes's model explicitly yield control to their concurrent 783 environment. Following Abadi and Plotkin [1], we investigated adding an addi-784 tional unary operator Y for yielding control to the concurrent environment. It 785 is natural to interpret Y as adding a no-op transition $\langle \sigma, \sigma \rangle$ before every trace 786 in its argument, modelling a possible interference by the environment. An alter-787 native choice is to add such no-op transitions and also keep the original traces, 788 modelling a *possibility* for a yield in the previous sense. Both of these options 789 trivialize in Brookes's model: 790

⁷⁹¹ **No-go 3.** Consider the following interpretations of Y in Brookes's model:

$$\left[\!\left[\mathsf{Y}\right]\!\right]_{\mathrm{op}}^{1}K \coloneqq \left\{ \langle \sigma, \sigma \rangle \tau \mid \tau \in K \right\} \qquad \left[\!\left[\mathsf{Y}\right]\!\right]_{\mathrm{op}}^{2}K \coloneqq K \cup \left[\!\left[\mathsf{Y}\right]\!\right]_{\mathrm{op}}^{1}K$$

Then $\llbracket Y \rrbracket_{\text{op}}^{i} K = K$ for both $i \in \{1, 2\}$, for any closed K.

⁷⁹³ *Proof.* K is closed under stutter and hush.

Even though Brookes's model does not support this intuition, we explored where the yield approach leads. With this yield operator, lookup and update can represent interference-free memory-access as axiomatized in the global-state theory, and surface-language level read and write can be modelled by some combination of the algebraic operators. Formally, let **Res** be a presentation that includes non-deterministic global state, and the yield operator Y, which is **Res**provably strict and distributes over joins.

Option 1 (Dvir et al.'s presentation [12]). For a previous theory of ours, we took a minimal Res satisfying our restrictions, and defined the algebraic representation of read:

$$\mathsf{R}_{\ell}(x_{0}, x_{1}) \coloneqq \left(x_{0}, x_{1} \vdash_{\Sigma_{\mathsf{Rec}}} \mathsf{L}_{\ell}((x_{0} \lor \mathsf{Y} x_{0}), (x_{1} \lor \mathsf{Y} x_{1})) \right)$$

⁸⁰⁴ Reading *may* admit an interference point after looking the value up in memory.

Option 2 (Plotkin's presentation [31]). Another natural option is to take Res to also prove that Y is a closure operator, i.e. $x \vdash_{\text{Res}} Y Y x = Y x \ge x$. In this option, the intuition for Y is that of a *possible* yield, and possibly yielding twice is the same as once. This theory allows the algebraic representation of read to be a bit more natural:

$$\mathsf{R}_{\ell}(x_{0}, x_{1}) \coloneqq \left(x_{0}, x_{1} \vdash_{\Sigma_{\mathsf{Res}}} \mathsf{Y} \,\mathsf{L}_{\ell}(\mathsf{Y} \, x_{0}, \mathsf{Y} \, x_{1})\right)$$

⁸¹⁰ Both options prove (Irrelevant Read Elim), but not (Irrelevant Read Intro):

$x \vdash_{Res} R_\ell(x,x) \geq x$	(Irrelevant Read Elim)
$x \not\vdash_{Res} R_\ell(x,x) \leq x$	(Irrelevant Read Intro)

Brookes's model validates (Irrelevant Read Intro), so the proposed theories are
both not abstract enough. Adding (Irrelevant Read Intro) as an axiom in either
version is problematic, as it implies the following inequation:

$$x \vdash_{\Sigma_{\mathsf{Res}}} \mathsf{R}_{\ell}(\mathsf{R}_{\ell}(x_{0,0}, x_{0,1}), \mathsf{R}_{\ell}(x_{1,0}, x_{1,1})) \leq \mathsf{R}_{\ell}(x_{0,0}, x_{1,1}) \qquad (\text{Same Read Intro})$$

The corresponding program transformation is invalid in our setting because the environment can interfere, mutating ℓ between the successive reads.

⁸¹⁶ We summarise this intermediate result:

⁸¹⁷ No-go 4. Let Res be either Dvir et al.'s or Plotkin's presentation, and define ⁸¹⁸ R_{ℓ} accordingly. if (Irrelevant Read Elim) and (Irrelevant Read Intro) are valid ⁸¹⁹ in Res, then so is (Same Read Intro).

Another approach is to add unary operators \triangleleft' and \succ' that delimit the memory accesses. Formally, let Del be a presentation that includes non-deterministic global state, and the delimiting operators \triangleleft' and \succ' , which are Del-provably strict and distribute over joins. Define the algebraic representation of read:

$$\mathsf{R}_{\ell}(x_0, x_1) \coloneqq \left(x_0, x_1 \vdash_{\Sigma_{\mathsf{Res}}} \lhd' \mathsf{L}_{\ell}(\rhd' x_0, \rhd' x_1) \right) \tag{\star}$$

This approach subsumes the two **Res** options suggested above, by using the axioms $x \vdash \lhd' x = x$ and $x \vdash \rhd' x = x \lor \forall Y x$ for Dvir et al.'s presentations; and using $x \vdash \lhd' x = \forall x$ and $x \vdash \rhd' x = \forall Y x$ for Plotkin's presentation. In both cases, and more generally whenever \lhd' and \succ' are given by a combination of joins and yields, they commute:

Lemma 30. Let t_1 and t_2 be $\{\lor, \mathsf{Y}\}$ -term over $\{x\}$. If $x \vdash_{\mathsf{Del}} \lhd' x = t_1$ and x $\vdash_{\mathsf{Del}} \rhd' x = t_2$, then $x \vdash_{\mathsf{Del}} \lhd' \rhd' x = \rhd' \lhd' x$.

Proof. Using the semilattice axioms and distributivity of Y over joins, every $\{\lor, \mathsf{Y}\}$ -term t over $\{x\}$ is **De**l-equal to a non-deterministic choice between terms of the form $\mathsf{Y}^n x$ for $n \in N_t \subseteq \mathbb{N}$. Both terms above are equal to the same term of this form, with $N = \{n_1 + n_2 \mid n_1 \in N_{\lhd' x}, n_2 \in N_{\triangleright' x}\}$.

Any alternative of Del for which \triangleleft' and \triangleright' commute is not satisfactory:

No-go 5. Let Del be a presentation that includes non-deterministic global state, and the unary operators \triangleleft' and \triangleright' , which Del proves to be strict, distribute over joins, and commute. With read from (\star) , if Del proves (Irrelevant Read Elim) and (Irrelevant Read Intro), then it proves (Same Read Intro).

Proof. Combining (Irrelevant Read Elim) and (Irrelevant Read Intro), we have $x \vdash_{\mathsf{Del}} \mathsf{R}_{\ell}(x,x) = x$. Using global-state, we have $x \vdash_{\mathsf{Del}} \mathsf{R}_{\ell}(x,x) = \triangleleft' \rhd' x$. Therefore, $x \vdash_{\mathsf{Del}} \triangleleft' \rhd' x = x$. They commute, so $x \vdash_{\mathsf{Del}} \rhd' \triangleleft' x = x$. Using global-state, we prove (Same Read Intro) in Del.

Therefore, any such theory Del is either unsound, or it fails to validate a transformation that Brookes's model does. Thus, when picking Del, we need to make sure that \lhd' and \triangleright' do not commute.

As a final option we cover here, we could take the axioms $x \vdash \lhd' \rhd' x = x$ and $x \vdash \rhd' \lhd' x \ge x$. These are like the closure pair axioms of our sharedstate presentation **S**, but without the sort discipline. The single-sorted signature allows ill-bracketed terms such as $x \vdash \lhd' \lhd' x$. Though it may be possible to axiomatize that all such terms are equal to \bot , a more principled way to avoid such terms is to use a two-sorted theory as we have.

The analysis we offered in this section does not rule out the possibility of a satisfactory single-sorted theory of shared-state. We hope that these considerations could inform future pursuit of this theory, or a tighter no-go result.

⁸⁵⁶ B Proof of the representation theorem

⁸⁵⁷ To start, we first prove proposition 23, soundness of encoded trace deductions:

Proof. First, standardly in G we have $x : \star \vdash_{\mathsf{G}} \{\sigma, \rho\} \{\rho', \theta\} x \ge \{\sigma, \theta\} x : \star$ and $x : \star \vdash_{\mathsf{G}} \{\sigma, \sigma\} x \ge x : \star$, which are included in the \bullet sort in S.

- The former, combined with Connect, leads to soundness of mumble.

- ⁸⁶¹ The latter, combined with Empty, leads to soundness of stutter.
- ⁸⁶² That reification is indifferent to closure follows:

Proposition 31. For $K \in \mathbf{P}_{\square}^{\aleph_0}(\mathbb{T}\mathbf{X}), \mathbf{X} \vdash_{\mathbf{S}} \operatorname{reify}_{\square} K = \operatorname{reify}_{\square} K^{\dagger} : \square$.

⁸⁶⁴ *Proof.* Follows from proposition 23 by inequational reasoning.

To prove the S-Rep. Thm., let $X \in \mathbf{Set}^{\{\bullet, \circ\}}$. We start by giving alternative formulas to the interpretations of the lock operators.

Lemma 32. Denote the set of sequences of transitions, where each transition has equal components $\mathbb{S}^*_{=} := \{ \langle \sigma, \sigma \rangle \mid \sigma \in \mathbb{S} \}^*$. The following hold:

$$\begin{split} \mathbf{R}\boldsymbol{X} \left[\!\left[\triangleleft \right]\!\right]_{\mathrm{op}} \boldsymbol{K} &= \left\{ \mathsf{o}\xi_{0}^{2}\boldsymbol{\xi} \diamond \boldsymbol{x} \mid \boldsymbol{\xi}_{0}^{2} \in \mathbb{S}_{=}^{*}, \boldsymbol{\bullet}\boldsymbol{\xi} \diamond \boldsymbol{x} \in \boldsymbol{K} \right\} \\ \mathbf{R}\boldsymbol{X} \left[\!\left[\succ \right]\!\right]_{\mathrm{op}} \boldsymbol{K} &= \left\{ \boldsymbol{\bullet}\boldsymbol{\xi} \diamond \boldsymbol{x}, \boldsymbol{\bullet} \langle \boldsymbol{\sigma}, \boldsymbol{\sigma} \rangle \boldsymbol{\xi} \diamond \boldsymbol{x} \mid \boldsymbol{\sigma} \in \mathbb{S}, \mathsf{o}\boldsymbol{\xi} \diamond \boldsymbol{x} \in \boldsymbol{K} \right\} \end{split}$$

⁸⁶⁹ Proof sketch. The fact that K is closed means that most trace deductions af-⁸⁷⁰ forded in the interpretations as defined in the **S**-Rep. Thm. are redundant.

- ⁸⁷¹ In $\mathbf{R} X \llbracket \triangleleft \rrbracket_{\text{op}} K$, the only application of a trace deduction that results in a ⁸⁷² trace that would is not in the set before taking the closure is one of stutter ⁸⁷³ at the start of the trace.
- ⁸⁷⁴ In $\mathbf{R} \mathbf{X} \llbracket \triangleright \rrbracket_{\text{op}} K$, the only application of a trace deduction that results in a ⁸⁷⁵ trace that would is not in the set before taking the closure is one of mumble ⁸⁷⁶ at the start of the trace.
- 877 Lemma 33. RX is an S-model.
- ⁸⁷⁸ Proof. This amounts to showing that $\mathbf{R}X$ validates every **S**-axiom.
- ⁸⁷⁹ The countable-join semilattice ones follow standardly for sets and unions.
- Commutativity follows from the fact that interpretations are all defined by
 direct images.
- The global state equations validate as they did in the model from Dvir et al. [12], where they were interpreted in a similar manner.
- 884 This leaves Empty:

$$\begin{split} \llbracket \lhd \rrbracket \ \llbracket \lhd \rrbracket \ K &= \ \llbracket \lhd \rrbracket \left\{ \bullet \xi \diamond x, \bullet \langle \sigma, \sigma \rangle \xi \diamond x \mid \sigma \in \mathbb{S}, \mathsf{o} \xi \diamond x \in K \right\} \\ &= \left\{ \mathsf{o} \xi_0^2 \xi \diamond x \mid \xi_0^2 \in \mathbb{S}_=^*, \bullet \xi \diamond x \in K \right\} = K \end{split}$$

where the last step is due to K being closed; and Connect:

$$\begin{split} \llbracket \triangleright \rrbracket \ \llbracket \lhd \rrbracket K &= \llbracket \triangleright \rrbracket \left\{ \mathbf{o}\xi_0^? \xi \diamond x \mid \xi_0^? \in \mathbb{S}_=^*, \mathbf{\bullet}\xi \diamond x \in K \right\} \\ &= \left\{ \mathbf{\bullet}\xi_0^? \xi \diamond x, \mathbf{\bullet}\langle\sigma,\sigma\rangle \xi_0^? \xi \diamond x \mid \xi_0^? \in \mathbb{S}_=^*, \mathbf{\bullet}\xi \diamond x \in K \right\} \supseteq K \end{split}$$

where the last step is by taking an empty ξ_0^2 in the first element.

- 26 Y. Dvir, O. Kammar, O. Lahav, and G. Plotkin
- We mention some equations regarding open transitions provable in S.
- *** Lemma 34. $x : \bullet \vdash_{\mathfrak{S}} \bigvee_{\sigma \in \mathbb{S}} \{\sigma, \sigma\} x = x : \bullet$
- ⁸⁸⁹ *Proof.* Follows from the global state validity: $x : \star \vdash_{\mathsf{G}} \bigvee_{\sigma \in \mathbb{S}} \{\sigma, \sigma\} x = x : \star.$
- B90 Lemma 35. $x : \mathsf{o} \vdash_{\mathfrak{S}} \bigvee_{\sigma \in \mathbb{S}} \lhd \{\sigma, \sigma\} \vartriangleright x = x : \mathsf{o}$
- ⁸⁹¹ *Proof.* Follows from ND- \triangleleft , lemma 34, and Empty.

Let's turn to the extension of environments along return. Let \mathbf{A} be an \mathbf{S} algebra, and let $e: \mathbf{X} \to \underline{\mathbf{A}}$ be an \mathbf{X} -environment in \mathbf{A} . Then:

- ⁸⁹⁴ Lemma 36. $e^{\#}$ is homomorphic.
- Proof. By evaluating both sides, it suffices to show that for every operator $(O : \Box \langle \Box_1, ..., \Box_{\alpha} \rangle) \in \Sigma_{\mathfrak{S}}$, and all $K_i \in \underline{\mathbf{R}X}_{\Box}$:

$$\boldsymbol{X}\vdash_{\boldsymbol{\mathbb{S}}} \operatorname{reify}(\mathbf{R}\boldsymbol{X}\left[\!\left[O\right]\!\right]_{\operatorname{op}}(K_1,\ldots,K_\alpha)) = O(\operatorname{reify}K_1,\ldots,\operatorname{reify}K_\alpha): \square$$

As in the proof of lemma 33, most follow as in Dvir et al.'s model [12], and we focus again on the interesting cases of \triangleleft and \triangleright . In both cases, we use proposition 31 to simplify. For the treatment of the \triangleright case below, we use lemma 34 in the third equation:

$$\begin{split} \boldsymbol{X} \vdash_{\boldsymbol{\mathfrak{S}}} \operatorname{reify}(\mathbf{R}\boldsymbol{X} \llbracket \triangleright \rrbracket_{\operatorname{op}} K) &= \operatorname{reify} \left\{ \bullet \langle \sigma, \sigma \rangle \xi \diamond x \mid \sigma \in \mathbb{S}, \mathsf{o}\xi \diamond x \in K \right\} \\ &= \bigvee_{\sigma \in \mathbb{S}, \mathsf{o}\xi \diamond x \in K} \left\{ \sigma, \sigma \right\} \triangleright \underline{\mathsf{o}\xi} \diamond x \\ &= \bigvee_{\sigma \xi \diamond x \in K} \triangleright \underline{\mathsf{o}\xi} \diamond x \\ &= \bigvee_{\mathsf{o}\xi \diamond x \in K} \triangleright \underline{\mathsf{o}\xi} \diamond x \\ &= \triangleright \bigvee_{\mathsf{o}\xi \diamond x \in K} \underline{\mathsf{o}\xi} \diamond x = \triangleright(\operatorname{reify} K) : \bullet \\ \boldsymbol{X} \vdash_{\boldsymbol{\mathfrak{S}}} \operatorname{reify}(\mathbf{R}\boldsymbol{X} \llbracket \lhd \rrbracket_{\operatorname{op}} K) = \operatorname{reify} \left\{ \mathsf{o}\xi \diamond x \mid \bullet \xi \diamond x \in K \right\} \\ &= \bigvee_{\bullet\xi \diamond x \in K} \lhd \underline{\bullet\xi} \diamond x \\ &= \lhd \bigvee_{\bullet\xi \diamond x \in K} \underline{\diamond} \underline{\mathsf{o}\xi} \diamond x = \lhd(\operatorname{reify} K) : \bullet \end{split}$$

901 Lemma 37. $e = e^{\#} \circ \text{return for all } x \in X$.

Proof. By evaluating in e the equations $x : \Box \vdash_{\mathbf{S}} \operatorname{reify}_{\Box}(\operatorname{return}_{\Box} x) = x : \Box$, which are easily verified in light of proposition 31, using lemmas 34 and 35.

904 Lemma 38. return[#] : $\mathbf{R}X \to \mathbf{R}X$ is the identity.

Proof sketch. Follows by calculation, mainly by showing that for any $K \in \underline{\mathbf{RX}}_{\bullet}$, we have that $\mathbf{R} \{x : \bullet\} \llbracket \{\sigma, \rho\} x \rrbracket_{\text{term}} (x \mapsto K) = (\sigma, \rho) K$.

Finally, we show uniqueness. Let $f : \mathbf{R}X \to \mathbf{A}$ be a homomorphism. Then:

908 **Lemma 39.** If $e = f \circ \text{return } then f = e^{\#}$.

Proof. We use the following notation. For any **S**-algebra **B** and $\tilde{e} : \mathbf{X} \to \mathbf{B}$, we denote $\operatorname{eval}(\tilde{e}) := \mathbf{B}[\![-]\!]_{\operatorname{term}} \tilde{e} : \operatorname{Term}^{\Sigma_{\mathfrak{S}}} \mathbf{X} \to \mathbf{B}$. Thus, $\tilde{e}^{\#} = \operatorname{eval}(\tilde{e}) \circ \operatorname{reify}$. Since $\operatorname{eval}(f \circ \operatorname{return}) : \operatorname{Term}^{\Sigma_{\mathfrak{S}}} \mathbf{X} \to \mathbf{A}$ is the only homomorphic extension

Since $\operatorname{eval}(f \circ \operatorname{return})$: $\operatorname{Term}^{\Sigma_{\mathfrak{F}}} X \to \mathbf{A}$ is the only homomorphic extension of $f \circ \operatorname{return} : X \to \mathbf{A}$ along the inclusion $\iota : X \hookrightarrow \operatorname{Term}^{\Sigma_{\mathfrak{F}}} X$, we have that $\operatorname{eval}(f \circ \operatorname{return}) = f \circ \operatorname{eval}(\operatorname{return})$. Using lemma 38:

 $e^{\#} = \operatorname{eval}(e) \circ \operatorname{reify} = \operatorname{eval}(f \circ \operatorname{return}) \circ \operatorname{reify} = f \circ \operatorname{eval}(\operatorname{return}) \circ \operatorname{reify} = f \quad \Box$

Putting everything together, $\langle \mathbf{R} \mathbf{X}, \text{return} \rangle$ is a **S**-model over \mathbf{X} (lemma 33) such that every environment homomorphically (lemma 36) extends along return (lemma 37), and does so uniquely (lemma 39). So $\langle \mathbf{R} \mathbf{X}, \text{return} \rangle$ is a *free* **S**-model over \mathbf{X} , proving the **S**-Rep. Thm.
